COPPERHEAD
ENVIRONMENTAL CONSULTING

Executive Summary

North Carolina Department of Transportation (NCDOT) contracted Copperhead Environmental Consulting, Inc. (Copperhead) to assist with portions of a research study of the federally threatened northern long-eared bat (*Myotis septentrionalis*; NLEB) in eastern North Carolina's Coastal Plain. Since the species presence was first documented in the Coastal Plain in 2007, relatively little is known of the natural history of the species in this region. This study is part of a multi-year research project designed to elucidate the distribution, habitat preferences, and behavior of the NLEB in the region. A detailed summary of the results of this field study are provided herein.

Copperhead conducted bat surveys at 2 pre-determined study areas using mist-netting techniques during "Fall" (15 November – 20 December 2017) and "Winter" (26 December 2017 – 28 February 2018) study periods. All surveys were conducted within suitable NLEB roosting and foraging habitat with the goal of capturing and radio-tagging individuals of the species. In general, mist-netting followed guidelines established by the US Fish and Wildlife Service (USFWS 2017). However, certain flexibility was made for nights when the temperatures fell below 50°F (10°C) during the fall and winter months.

Netting efforts were conducted at 18 sites over 85 crew nights. A total of 153 bats of 7 species were captured, including 17 NLEB. Twelve NLEB were fitted with radio transmitters (10 temperature sensitive transmitters and 2 non-temperature sensitive transmitters) and subsequently tracked in an effort to locate day roosts and characterize habitat preferences. Copperhead crews used ground-based and aerial telemetry to locate radio-tagged bats. Seven of the focal bats were successfully tracked for ≥ 21 days. Of the remainder, 1 transmitter was shed after 10 days, 1 transmitter died after 13 days, and 2 bats went missing for several days before aerial searches were able to relocate them. One bat was never detected or successfully tracked from the ground but was located with the plane on 2 occasions.

Tracking efforts successfully located 54 roost trees of 13 tree species in 1 study area (Alligator River National Wildlife Refuge, Dare County), and no NLEB were caught in the second study area (Gull Rock Game Land, Hyde County). The mean number of roosts used by focal bats was 5 (range 1 – 9 roosts). The mean number of days focal bats remained in a roost was 3.8 (range 1 – 16 days). A minimum of 1 emergence count was conducted on each roost tree. The maximum number of bats observed emerging from a roost was 1. The mean distance from point of capture to day roosts (including triangulations and aerial estimates) was 1,341 m (range 114 – 13,853 m).

All bats were captured when ambient temperature was $\geq 51.1^\circ\text{F}$. Radio-tagged bats were recorded as being awake at ambient temperatures as low as 37.6°F .

Project Background

The US Fish and Wildlife Service (USFWS) formally listed the northern long-eared bat (*Myotis septentrionalis*; NLEB) as a threatened species under the Endangered Species Act on 4 May 2015. Subsequently, the North Carolina Department of Transportation (NCDOT) entered into a Programmatic Agreement with the USFWS that includes a research program designed to establish conclusive information concerning the existence of the NLEB in the Coastal Plain of North Carolina. NCDOT has funded NLEB surveys during the summer and winter months to better understand the species' habitat requirements.

The NLEB was first documented in the Coastal Plain of North Carolina in 2007 (Morris et al. 2009). While most NLEB across their range hibernate underground, the Coastal Plain has no known caves or mines. Subsequent research (NCDOT 2016, Three Oaks 2016, Copperhead 2017) has shown that a population of the species overwinters on the Coastal Plain where the relatively mild winter temperatures appear to allow a level of insect activity high enough to provide winter foraging opportunities (Grider 2016).

In October 2017, Copperhead Environmental Consulting, Inc. (Copperhead) was contracted by NCDOT to conduct a mist-net survey at 2 predetermined study sites in the Coastal Plain of North Carolina. The Fall 2017/Winter 2018 NLEB Research Project (detailed herein) represents the 5th phase of an ongoing multi-year effort to elucidate the range, habitat preferences, and behavior of the species in the Coastal Plain of North Carolina. The objectives of this study outlined by NCDOT in the provided Scope of Work include the following:

- Determine the distribution of NLEB in eastern North Carolina, further document fall/winter activity, and develop a greater understanding of NLEB winter habitat use and behavior;
- Conduct mist-netting and radio telemetry on NLEB to locate and characterize day roosts used during the late fall/winter months;
- Determine how NLEBs respond if/when ambient air temperatures drop below 50°F using temperature sensitive transmitters;
- Swab susceptible bats in winter to determine presence/absence of *Pseudogymnoascus destructans* (*Pd*), the fungus that causes white-nose syndrome (WNS).

Study Area Description

Copperhead was tasked with sampling 2 locations in the Coastal Plain of North Carolina:

1. Alligator River National Wildlife Refuge, Dare County
2. Gull Rock Game Land, Hyde County

Both study areas had previously been surveyed during the summer with acoustic and/or mist-net surveys, and NLEB had been captured at a single site in both study areas.

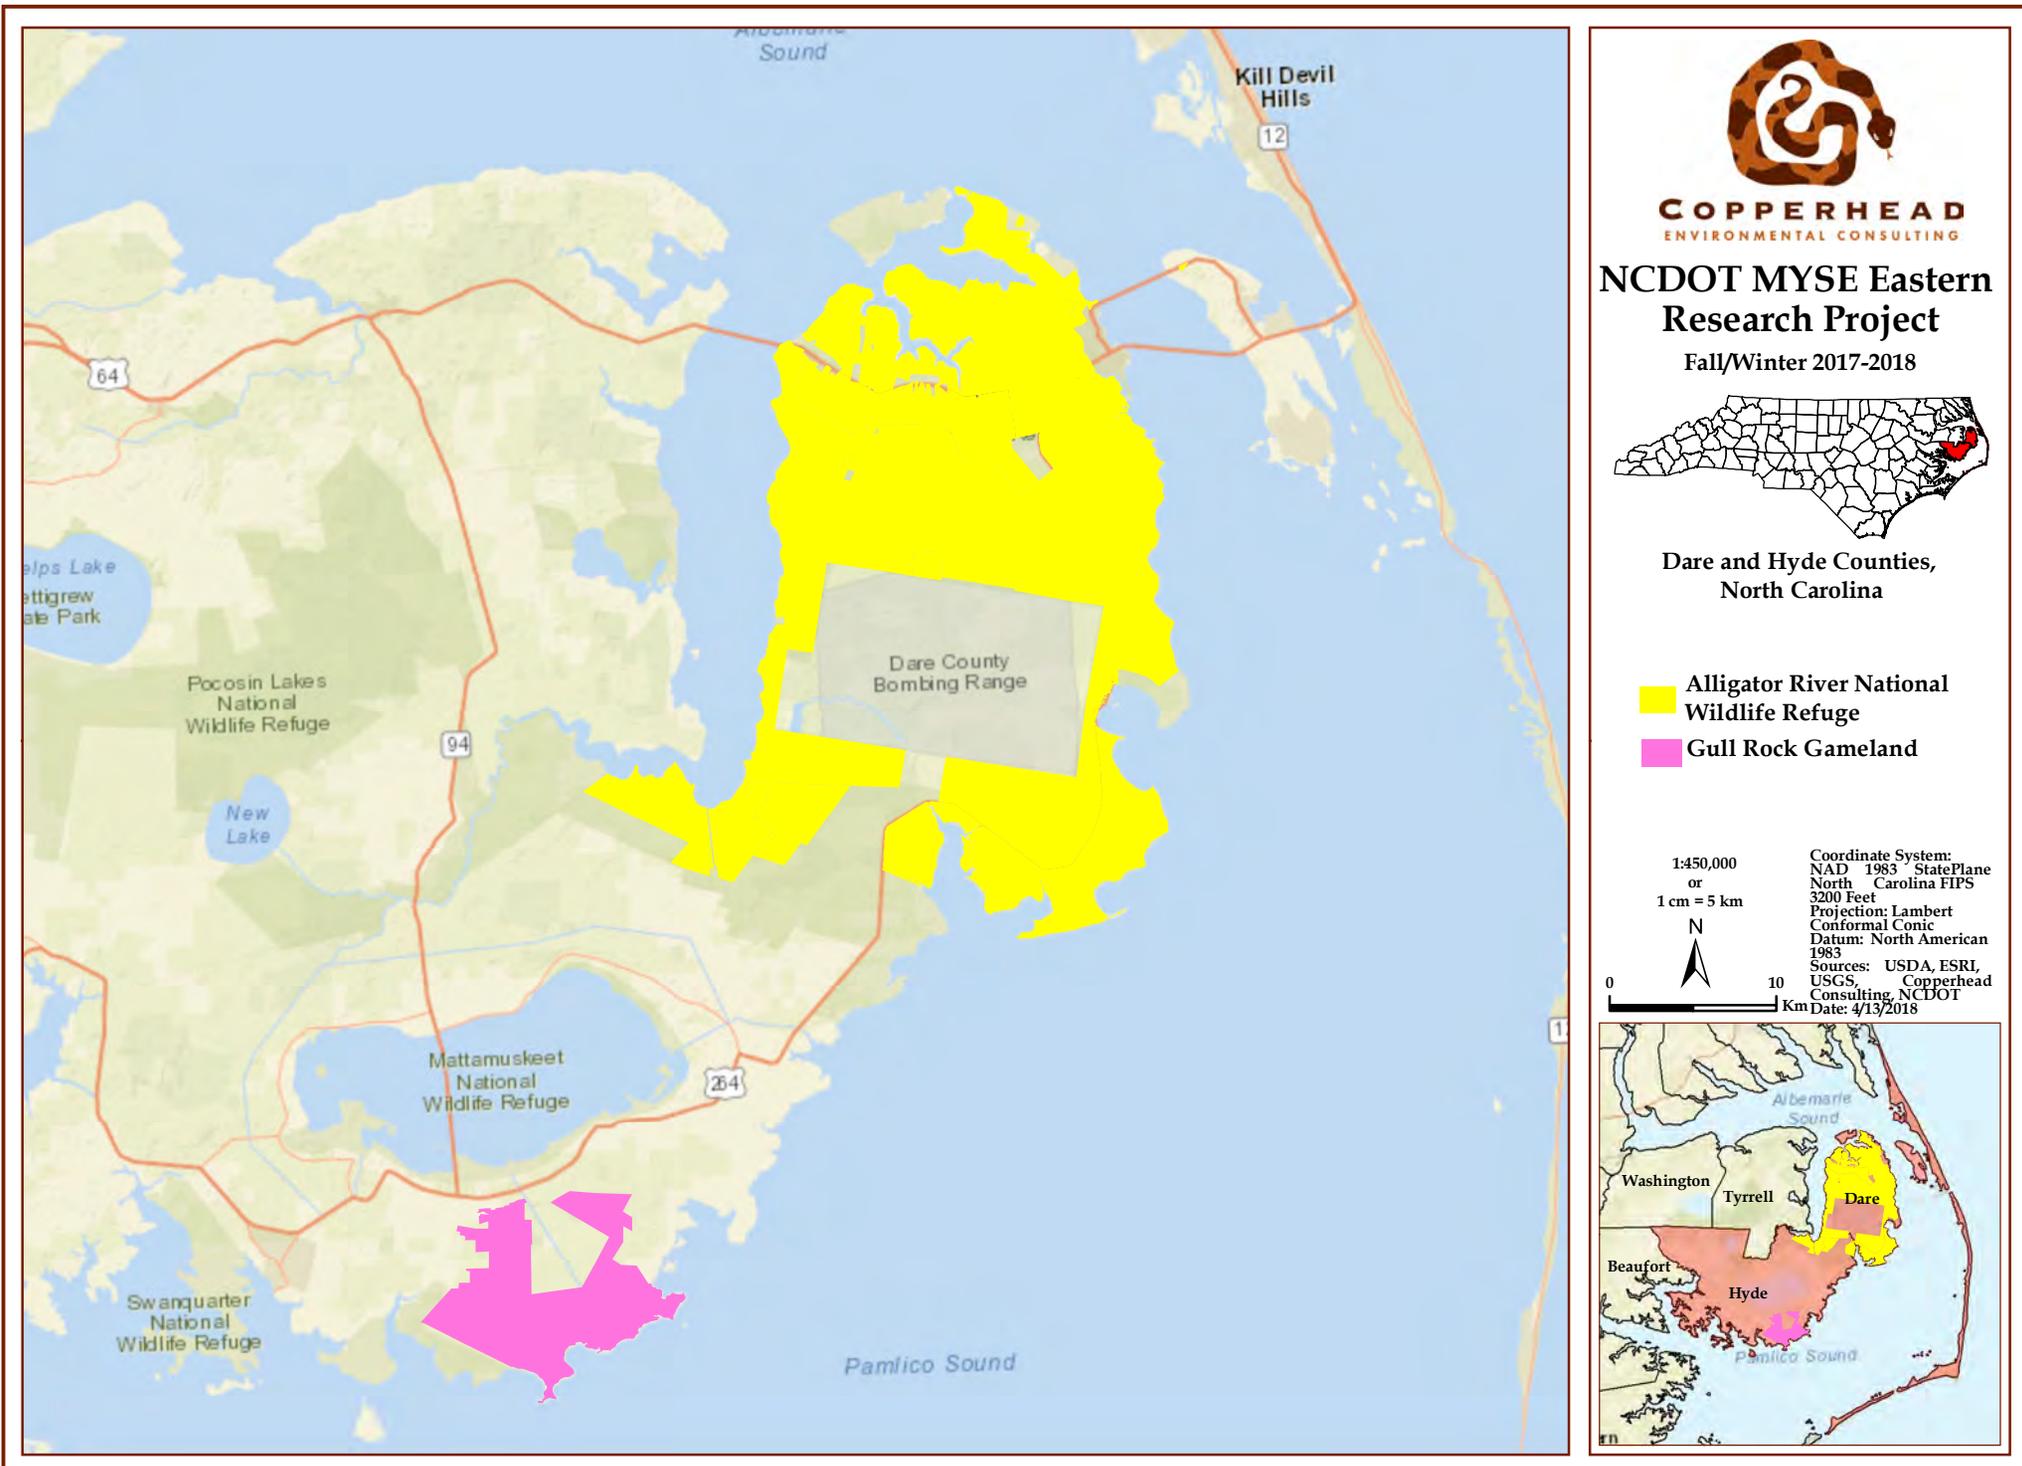

Figure 1. Project overview and study areas surveyed during the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare and Hyde counties, North Carolina.

Methods

Mist-Net Surveys

Mist-net surveys generally followed methodologies outlined by the *2017 Range-Wide Indiana Bat Summer Survey Guidelines* (USFWS 2017). In some cases, NCDOT requested modifications to the guidelines to allow netting during colder nightly temperatures during the fall and winter months. Mist-net surveys were conducted over 85 crew nights at 18 sites across the 2 study areas. A crew night is defined as 1 crew at 1 site for a complete survey night. The 18 sites included 2 sites where NLEB had been captured in earlier studies conducted in the summers. The 16 remaining sites were determined via discussions with ARNWR biologists and field reconnaissance by Copperhead biologists in areas of suitable NLEB habitat.

Mist-nets were set to maximize coverage of flight paths used by NLEB along suitable travel corridors, foraging areas, or drinking areas. The placement of mist-nets was based on the extent of canopy cover, presence of an open flyway, and forest conditions near the site. The actual location and orientation of each net was determined in the field. Mist-net sites were surveyed for 1 or more nights based on capture success and/or the quality of surrounding habitat. All work was conducted by qualified bat biologists with current applicable USFWS and North Carolina Wildlife Resources Commission (NCWRC) permits.

A minimum of 4 net sets were deployed each night. Each set consisted of a minimum of 1 double-high net configuration (i.e., 2 nets stacked; 5.2 m tall). Low visibility, high-quality nylon nets, 4 to 12 m (depending upon the width of the corridor), were used for each net set. Nets were deployed at sunset each night, left open for the duration of the survey period, and checked every 10 minutes. Disturbance near the nets was kept to a minimum between checks.

Weather data, including temperature, wind speed, and cloud cover, were recorded at each site on an hourly basis to ensure compliance with the mist-netting guidelines. In the fall survey period, no work was conducted on nights when the forecasted temperature at sunset was lower than 50°F. During the winter survey period, no work was conducted on nights when the forecasted temperature at sunset was lower than 45°F. Nightly mist-net efforts at each site were considered “complete” when nets remained open for at least 5 hours past official sunset. If temperatures fell below 45°F, netting was ceased and only considered a complete night if temperatures in the first 3 hours of survey stayed above 45°F. Survey efforts at each site were repeated if weather conditions failed to meet the minimum temperature requirement, the winds moved the nets more than 50 percent of the time, or rain or fog persisted for 30 minutes or continued intermittently throughout the survey period.

Bats were live-caught in mist-nets and released unharmed near the point of capture. Data was recorded on NCDOT Mist-Netting Data Forms. Biological and morphometric data collected included species, sex, age class (juvenile or adult), reproductive condition

(pregnant, lactating, post-lactating, scrotal, or non-reproductive), forearm length (mm), and mass (g). Wing-Damage Index (WDI) was scored and recorded for each bat based on Reichard and Kunz (2009) to determine possible White-nose Syndrome (WNS) infection. In addition, the capture height and the specific net set of capture were recorded for each bat. Processing of bats was completed within 30 minutes from the time the bat was removed from the net. Aluminum-lipped arm bands (Porzana Ltd, Icklesham, East Sussex, UK) provided by NCDOT and Copperhead were applied to the right (for males) or left (for females) forearm of captured bats.

Prior to release, NLEB were photographed following USFWS (2017) techniques. Mist-netting was considered complete after the target number of NLEBs were radio-tagged ($n = 6$) during each survey period.

Radio Telemetry

All radio-transmitters used during the study were programmed to 172 kHz. NLEB ≥ 6.5 g were fitted with temperature-sensitive 21-day radio transmitters (Holohil Systems Ltd. LB-2X, 0.33 g). NLEB that were 6.0 - 6.5 g were fitted with 15-day transmitters (Holohil Systems Ltd. LB-2X, 0.27 g; Lotek Wireless Inc. PicoPip, 0.29 g). Transmitter attachment followed methodologies outlined in the *2017 Range-wide Indiana Bat Summer Survey Guidelines* (USFWS 2017). Radio transmitters were tested and then attached between the scapulae of each bat using a nontoxic surgical adhesive (The Perma-Type Company, Inc., Plainville, CT, USA) that degrades over time allowing the transmitter to eventually become detached from the bat. The unique frequency of each transmitter was used to identify individual bats during radio-tracking.

Ground Telemetry

Model TRX-1000S (Wildlife Materials Inc., Carbondale, Illinois, USA) and model R-1000 (Communications Specialist Inc., Orange, California, USA) tracking receivers and 172-3FB 3- and 5-element Yagi directional antennas were used to search for radio-tagged bats. Diurnal roosts were located for radio-tagged bats for at least 21 days, or the transmitter was shed or malfunctioned, whichever occurred first. Five bats were tracked beyond 21 days with approval from NCDOT and USFWS. If radio signals were not immediately detected in the field, the bat was searched for on the ground for 4 - 8 hours.

Roost trees were photographed, and coordinates were obtained using a handheld GPS unit set to decimal degrees using the NAD83 datum. In addition, a sketch of the roost tree was made on Copperhead's Roost Tree Datasheet and a uniquely numbered aluminum tree tag and high visibility flagging were placed on each tree to aid in locating trees in the future. Basal area [an expression of tree density (Avery 1967)] of the forest surrounding the roost tree was determined with a 10-factor prism. A basal area prism was used to determine a variable radius plot around the roost tree. All trees within the plot were identified to species and the following data was recorded for each tree: diameter at breast height (dbh; in cm), tree height (in m; estimated), roost height (in m; estimated if known), condition (i.e., snag, live, or live-damaged), percent usable bark cover for roosting

(Gardner et al. 1991), percent total bark cover, tree ranking (i.e., whether a tree's crown was in the canopy, sub-canopy, or understory), and any other noteworthy observations (e.g., bat vocalization, guano). Emergence counts were documented on USFWS Emergence Count Datasheets (USFWS 2017) and Copperhead Roost Tree Datasheets.

Bat Body and Air Temperature Data Collection

Model R4500SD Receiver - Dataloggers (Advanced Telemetry Systems Inc., [ATS], Isanti, MN) were deployed 1 day after bat capture in the vicinity of a roosting area in order to collect interpulse periods of temperature sensitive transmitters. These data were used in a 3rd order polynomial equation created from calibration points provided by the manufacturer to determine bat body temperature. A strong, constant signal is required for logging of these inter-pulse periods. Therefore, even though a datalogger could hear the transmitter signal, the signal while a bat was actively flying and foraging was not always consistent enough to record the inter-pulse periods. Data collection of bats at rest was more consistent and provides insight into a number and duration of behavior states (i.e., awake or torpor). Tracking crews checked the R4500SD data loggers and downloaded data daily.

To collect ambient air temperature and humidity in coordination with the collection of bat temperature, DS1923 iButton® Temperature/Humidity data loggers (Maxim Integrated, San Jose, CA) were placed on the landscape near roosting bats. iButton® data loggers were collected and downloaded at the end of each survey period.

Bat activity was determined from the recorded bat temperatures and air temperatures using the torpor on-set equation by Willis (2007):

$$T_{\text{body-onset}} - 1 \text{ SE} = (0.041)\text{body mass} + (0.040)T_{\text{air}} + 31.083$$

A bat temperature was considered "awake" if the recorded bat temperature was > torpor on-set temperature and considered "torpid" if the recorded bat temperature was < torpor on-set temperature.

Aerial Telemetry

If ground crews lost contact with a transmitter for more than 2 days, aerial searches were conducted to relocate the lost bat. Aerial searches were conducted using a Cessna Sky Hawk 172 fitted with ATS aircraft strut mount assemblies with 2 172-3FB 4-element ATS Yagi directional antennas (model #13886). The aerial crew consisted of a pilot and a navigator. The pilot maintained an elevation of approximately 455 m above ground level and the navigator monitored the transmitter signal through the receiver, estimating bat location on mapping software (DeLorme Topo North America 9.0, Yarmouth, ME). The aerial crew performed a search pattern along parallel transects spaced approximately 6 km apart centered on the last known location of the lost bat. This pattern, distance, and altitude is well within known signal capabilities and allowed for maximum coverage of the landscape.

Habitat Characterization

The natural community type was described at all NLEB capture sites and day roosts. Community types followed the *Guide to the Natural Communities of North Carolina, Fourth Approximation* (Schafale 2012). In addition, habitat in the survey area was characterized using the following attributes:

- 1) pine/hardwood/mixed
- 2) upland/bottomland
- 3) managed (thinned, burned, or pine plantation)/unmanaged
- 4) cutover/immature forest/mature forest
- 5) natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)
- 6) clutter (classifications 1-4):
 - sparse/no, < 10% cover
 - low, 10-39% cover
 - medium, 40-75% cover
 - high, >75% cover

Clutter at mist-net sites was recorded as an average number representing the surrounding forest where all nets were set, not just the flyway.

White-Nose Syndrome Protocol

To minimize the transmission of WNS between captured bats, all netting and field activities followed the most recent USFWS *National White-Nose Syndrome Decontamination Protocol*. All hard, non-porous netting equipment was sanitized with Isopropyl alcohol wipes (70%) prior to arrival at the project site and after each survey night; all other equipment was submersed in hot water (140°F) for a minimum of 20 minutes. Disposable latex gloves were worn over sanitized handling gloves and changed following the handling of each bat. All non-disposable equipment (e.g., PESOLA® scales, rulers, calipers) which came into contact with bats was sanitized immediately following the handling of each bat.

Biological Sampling

Swab samples were collected from all captured NLEB and attempts were made to collect both swab and guano samples from captured little brown bats (*Myotis lucifugus*), southeastern bats (*Myotis austroriparius*), big brown bats (*Eptesicus fuscus*), and tricolored bats (*Perimyotis subflavus*). Collection methodologies followed guidance outlined in Appendix E of *North Carolina's White-nose Syndrome Surveillance and Response Plan, April 2016*. Collected swab samples were refrigerated and sent to the Southeast Cooperative Wildlife Disease Study (SCWDS) lab in the fall and to Kennesaw State University in the winter for *Pd* analysis under the NCWRC contract. Guano samples were also collected for *Pd* analysis from the species listed above in the fall survey session when available. Guano samples are currently being housed at the Copperhead Main Office pending

further shipping instructions from NCDOT or the US Geological Survey National Wildlife Health Center.

Results

Mist-Net Surveys

A total of 153 bats of 7 species were captured (Table 1). A detailed mist-net capture summary table is provided in Appendix A. Figures detailing the locations of mist-net sites and NLEB captures are provided in Appendix B and completed mist-net datasheets are provided in Appendix C. Photographs of mist-net sites are in Appendix D and photos of captured NLEB are provided in Appendix E.

Table 1. Summary of total bat captures by species, age, sex, and reproductive status captured during the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare and Hyde counties, North Carolina.

Species	Adult Male		Adult Female				Escaped	Total
	NR	S	P	L	PL	NR		
<i>Corynorhinus rafinesquii</i>	1	4	-	-	-	3	1	9
<i>Eptesicus fuscus</i>	21	8	-	-	-	13	-	42

<i>Perimyotis subflavus</i>	1	-	-	-	-	-	-	1
Total	82	21	0	0	0	45	5	153

* NR = non-reproductive, S = scrotal, P = pregnant, L = lactating, PL = post-lactating

Bat Capture by Study Area

A total of 18 sites were sampled across the 2 study areas (Table 2). The Alligator River NWR was surveyed in both the fall and winter study periods, while the Gull Rock Game Land was only surveyed in the winter study period. Because the required number of NLEB were captured and radio-tagged early in the fall study period at Alligator River NWR, NCDOT and USFWS agreed that capture efforts at the Gull Rock Game Land study area should be postponed until the winter survey period.

Table 2. Bat capture by study area during the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare and Hyde counties, North Carolina.

Study Area	Total Bat Captures	Species Richness	No. of Net Sites	No. of Crew Nights	# NLEB Captured
Alligator River NWR	110	7	13	60	17
Gull Rock GL	43	5	5	25	0
Total	153	7	18	85	17

Bat Capture by Study Period

During the fall study period, a total of 22 bats of 6 species were captured, including 8 red bats (*Lasiurus borealis*), 7 NLEB, 3 evening bats (*Nycticeius humeralis*), 2 Seminole bats (*L. seminolus*), 1 big brown bat, and 1 tri-colored bat. The average ambient temperature when bats were captured in the fall survey period was $59 \pm 33^\circ\text{F}$ (range $52 - 65^\circ\text{F}$). A tri-colored bat was caught at 52°F on December 15, 2017, which was the lowest temperature for a capture during the fall study period. The lowest temperature a NLEB was captured at was 53°F , also recorded on December 15, 2017.

During the winter study period, a total of 131 bats of 6 species were captured, including 48 evening bats, 41 big brown bats, 15 red bats, 10 NLEB, 9 Rafinesque’s big-eared bats (*Corynorhinus rafinesquii*), and 8 Seminole bats. The average ambient temperature when bats were captured in the winter study period was $61.5 \pm 32.5^\circ\text{F}$ (range $51 - 71^\circ\text{F}$). The lowest capture temperature during mist-netting efforts during this period was 51°F , recorded upon the capture of 2 Seminole bats on January 22, 2018 and NLEB captured on February 19 and 22, 2018.

On average, NLEB caught in the fall ($n = 7$) weighed more (8.3 ± 0.2 g; range 7.5 - 9.3 g) than those caught in the winter ($n = 10$; 6.2 ± 0.1 g; range 5.8 - 7.0 g).

Radio-telemetry, Roosts, and Emergence Counts

Twelve NLEB were fitted with radio-transmitters and tracked to locate their day roosts. Seven of the focal bats were tracked for 21 days or more, 1 transmitter was shed after 10 days, 1 transmitter died after 13 days, and 2 bats went missing for several days before aerial searches were able to locate them. The 12th bat was never heard from on the ground but was located during aerial searches on 2 occasions.

A total of 54 roost trees of 13 tree species were located by ground crews. The location of 3 additional roost locations were estimated via triangulation or from the airplane. This total includes 35 roost trees of 9 species located in the fall and 19 roost trees of 7 species located in the winter survey period. Roost trees varied greatly in size. Overall, the most commonly used species were *Nyssa biflora* ($n = 19$), *N. aquatic* ($n = 11$), *Persea palustris* ($n = 5$), and *Acer rubrum* ($n = 5$). Most roosts were live or live-damaged ($n = 48$) but focal bats also roosted in snags ($n = 6$). The mean dbh of all roost trees was 19.9 ± 1.5 cm (range

4.9 – 63.5 cm) and the mean tree height was 11.9 ± 0.70 m (range 3.5 – 24.0 m). Microhabitat used by NLEB included cavities (n = 35), cracks/crevices (n = 13), and exfoliating bark (n = 5).

The mean number of roosts used by all focal bats during both study periods was 5 (range 1 – 9 roosts). In general, focal bats roosted near their capture site and utilized multiple roosts close to one another. The mean distance from point of capture to day roosts (including triangulation and aerial estimates) was $1,341 \pm 337.9$ m (range 114 – 13,853 m). Bats switched roosts on average every 3.8 days (range 1 – 16 days) and many left roosts only to return to them another day.

In the fall study period, the most commonly used tree species were *Nyssa biflora* (n = 13), *N. aquatic* (n = 10), and *Liquidambar styraciflua* (n = 5). In the winter study period, *Nyssa biflora* (n = 6) was again the most commonly used tree species followed by *Persea palustris* (n = 4) and *Acer rubrum* (n = 3). On average, roost trees used in the fall and winter study periods were similar in DBH and tree height (Table 3).

Bats in the fall tended to use more roosts than in winter (Table 3). Average distance traveled from the point of capture to a day roost (Table 3) was greater in the winter (range 622 – 13,853 m) than in the fall (range 114 – 3,131 m).

Table 3. Select roost tree information by study period during the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare County, North Carolina. Distance from capture site includes estimated locations from triangulation and aerial telemetry.

Study Period	Mean \pm Standard Error			
	DBH (cm)	Tree Height (m)	# roosts used	distance from capture site (m)
Fall	18.5 ± 1.6	11.9 ± 0.9	5.8 ± 0.8	660.0 ± 148.0
Winter	22.5 ± 2.9	11.9 ± 1.1	3.6 ± 0.8	$2,592.0 \pm 869.6$

A total of 76 emergence counts were conducted (36 in the fall and 40 in the winter), including at least 1 survey at every roost location except for 1 tree. No more than 1 bat was observed emerging from a given roost. On multiple occasions, crews confirmed emergence via receiver and antenna because it was too dark and/or cluttered to see the bat emerge.

Completed roost tree and emergence datasheets are provided in Appendix F and photographs of day roosts are provided in Appendix G.

Bat Body and Air Temperature

In the fall study period, 6 NLEB were fitted with temperature-sensitive transmitters. ATS receiver dataloggers that were placed near each bat’s roosting area while a transmitter was active, recorded 99,339 bat temperatures from November 16 – December 20, 2017. Using the Willis (2007) equation for torpor on-set to determine if a bat was awake or in torpor, 976 recordings identified bats as awake. In the winter, 4 NLEB were fitted with temperature sensitive transmitters and ATS receiver dataloggers recorded 48,802 bat temperatures from February 8 – March 14, 2018. Of these, 1,102 recordings identified bats as awake.

Average air temperature when bats were in torpor during the fall study period was $49.6 \pm 32.0^{\circ}\text{F}$ (range $-28.4 - 78.9^{\circ}\text{F}$). Average air temperature when bats were awake during the fall study period was $58.1 \pm 32.1^{\circ}\text{F}$ (range $37.4 - 74.5^{\circ}\text{F}$). Average air temperature when bats were in torpor during the winter study period was $49.7 \pm 32.0^{\circ}\text{F}$ (range $-25.7 - 81.7^{\circ}\text{F}$). Average air temperature when bats were awake during the winter study period was $71.9 \pm 32.1^{\circ}\text{F}$ (range $38.4 - 81.6^{\circ}\text{F}$).

The coldest temperatures when a bat was recorded as awake were 37.4°F (fall study period) and 38.4°F (winter study period). The corresponding bat body temperatures for these recordings were 90.9°F and 92.6°F respectively (Table 4).

Table 4. Coldest air temperature recorded and corresponding bat body temperature while a bat was awake during the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare County, North Carolina.

Bat Frequency	Air Temperature °F	Bat Body Temperature °F	Date
172.664	51.0	96.7	11/25/2017
172.722	47.5	97.5	11/28/2017
172.063	48.4	91.8	11/29/2017
172.124	46.6	90.1	12/6/2017
172.603	37.4	90.9	12/9/2017
172.783	42.0	89.3	12/19/2017
172.905	43.9	90.0	2/12/2018
172.302	54.6	93.2	2/22/2018
172.182	55.6	90.6	2/23/2018
172.243	38.4	92.6	3/5/2018

The coldest air temperature recorded during the fall study period while a bat was torpid was 28.4°F and 25.7°F in the winter study period. During these coldest recorded temperatures, tagged bats’ body temperatures dropped to a low of 45.2°F in the fall and 50.8°F in the winter (Table 5).

Table 5. Coldest air temperature recorded and corresponding bat body temperature while a bat was torpid during the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare County, North Carolina.

Bat Frequency	Air Temperature °F	Bat Body Temperature °F	Date
172.664	33.0	46.3	11/21/2017
172.722	28.4	45.2	12/13/2017
172.063	31.2	50.1	11/27/2017
172.124	30.3	52.0	12/10/2017
172.603	30.3	55.8	12/10/2017
172.783	28.4	49.4	12/13/2017
172.905	27.6	51.4	2/9/2018
172.302	25.7	51.5	3/6/2018
172.182	35.7	58.0	3/9/2018
172.243	25.7	50.8	3/6/2018

The number of nights a bat broke torpor while being monitored ranged from 1 - 8. Torpor bouts ranged from 3-13 days. The longest torpor bout recorded in the fall was 12 (range 3-12) and 13 (range 2-13) in the winter (Table 6).

Table 6. Number of nights in torpor, number of arousals, the longest recorded torpor bout, and the number of days tracked for each bat in the Fall 2017/Winter 2018 NCDOT Northern Long-eared Bat Research Project, Dare County, North Carolina. Results based on recorded activity from the ATS receiver datalogger. If the datalogger was not recording during normal activity hours (sunset-sunrise), it was not included.

Bat Frequency	# nights in torpor	# nights awake	Longest torpor bout (days)	# days tracked
172.664	5	5	3	10
172.722	19	3	9	28
172.063	19	2	6	30
172.124	15	2	8	23

NLEB Capture Site Results and Habitat Characterizations

This section describes the mist-net sites within the Alligator River NWR where NLEB were documented (no NLEB were documented in the Gull Rock Game Land survey area).

Community type narratives are not provided for mist-net sites where no NLEB were captured. In the following sections, the letter/number combination after each bat represents band numbers of which NCDOT means that bands were provided by North Carolina DOT and CC = Copperhead Consulting.

ARNWR01 (35.827897, -75.903003) is in the northcentral part of the refuge. The mist-net site was positioned south of Sandy Ridge Road and south of a series of 4 narrow freshwater ponds. The surrounding forest most closely resembled a Blackwater Bottomland Hardwoods (High Subtype) Forest with dominant species including *Ilex* spp., *Liquidambar styraciflua*, *Morella cerifera*, *Pinus taeda*, and *Quercus* spp. It was a mature forest with 40-75% canopy cover. Five NLEBs were caught on 4 different nights: on November 15, 2017, 1 female (NCDOT1360) caught in net D was fitted with transmitter 172.603 and 1 male (CC1700) caught in net A was fitted with transmitter 172.664; on November 18, 2017, 1 female (CC1453) caught in net C was fitted with transmitter 172.124; on November 21, 2017, 1 male (CC1691) caught in net E was fitted with transmitter 172.783; and on February 7, 2018, 1 male (CC0100) caught in net B was fitted with transmitter 172.905. This site location was provided by USFWS and was the only site within the Alligator River NWR where previous studies had caught NLEB.

ARNWR02 (35.83055, -75.90145) is in the northcentral part of the refuge. This mist-net site was set up on Sandy Ridge Road, adjacent and north of a series of 4 narrow freshwater ponds. The surrounding forest most closely resembled a Blackwater Bottomland Hardwoods (High Subtype) Forest transitioning into a mix of a Bay/Cypress-Gum Swamp (Blackwater Subtype) with dominant species including *Liquidambar styraciflua*, *Magnolia virginiana*, *Nyssa* spp., and *Pinus* spp. One male NLEB (CC1451) was caught in net C on November 15, 2017 and fitted with transmitter 172.063.

ARNWR05 (35.80357, -75.88571) is in the northcentral part of the refuge. The mist-net site was set up on a dirt road adjacent to Miltail Road. This short dirt road led to an opening and there was water on either side of the dirt road. The surrounding forest most closely resembled a Blackwater Bottomland Hardwoods (High Subtype) Forest with dominant species including *Acer rubrum*, *Liquidambar styraciflua*, and *Pinus taeda*. The forest was mature with 40-75% canopy cover. Two NLEBs were caught on 2 different nights: on November 18, 2017, 1 male (CC2103) caught in net A was fixed with transmitter 172.722; and on February 19, 2018, 1 male (CC2110) caught in net B was fixed with transmitter 172.741 (a Holohill non-temperature sensitive transmitter).

ARNWR06 (35.831415, -75.904015) is in the northcentral part of the refuge. The mist-net site was positioned on an overgrown portion of Sandy Ridge Road where a water channel ran parallel to the north side of the road and forested wetlands were present to the north of the channel and south of the road. The surrounding forest most closely resembled a Blackwater Bottomland Hardwoods (High Subtype) Forest transitioning into a mix of a Cypress-Gum Swamp (Blackwater Subtype) with dominant species including *Ilex* spp., *Liquidambar styraciflua*, *Lyonia lucidula*, *Morella cerifera*, *Nyssa* spp., *Pinus* spp., *Quercus*

spp., and *Taxodium distichum*. The forest was mature with 40-75% canopy cover. Two NLEBs were caught on 2 different nights: on November 21, 2017, 1 male (CC2107) caught in net B was not fixed with a transmitter because another site had already caught the final NLEB needed for the fall study period; and on February 15, 2018, 1 male (CC0101) caught in net D was not fixed with a transmitter because the bat was < 6.0 g.

ARNWR09 (35.79123, -75.87230) is in the center of the refuge north of the Dare County Bombing Range. The net site was positioned on the dirt road portion of West Widgeon Road where it intersects with Cedar Rd. Wet channels run parallel to either side of both roads. The forest surrounding this site most closely resembled a Peatland Atlantic White Cedar Forest with dominant species including *Chamaecyparis thyoides*, *Persea palustris*, and *Pinus taeda*. The forest was mature with 40-75% canopy cover. Two NLEBs were caught on 2 different nights: on February 19, 2018, 1 male (CC0711) caught in net C was fixed with transmitter 172.302; and on February 22, 2018, 1 male (CC1725) caught in net D was not fixed with a transmitter because the bat weighed <6.0 g.

ARNWR10 (35.79755, -75.85710) is in the center of the refuge. The net-site was positioned on an unmaintained dirt road adjacent to West Widgeon Road. A wet channel ran parallel to the dirt road along its southeastern edge. The forest surrounding the net site most closely resembled a mix of a Blackwater Bottomland Hardwoods (High Subtype) Forest and a Peatland Atlantic White Cedar Forest with dominant species including *Acer rubrum*, *Chamaecyparis thyoides*, *Gordonia lasianthus*, *Ilex* spp., *Liquidambar styraciflua*, *Lyonia ligustrina*, *Morella cerifera*, *Persea palustris*, and *Pinus* spp. The forest was mature with greater than 75% canopy cover. One male NLEB (CC1723) caught in net A on February 19, 2018 was not fixed with a transmitter because it weighed <6.0 g.

ARNWR11 (35.83192, -75.90908) is in the north-central part of the refuge. The mist-net site was positioned on an overgrown portion of Sandy Ridge Road. A water channel runs parallel to the north side of the road and forested wetlands were present to the north on both sides of the road. The forest surrounding this site most closely resembled a Blackwater Bottomland Hardwoods (High Subtype) Forest transitioning into a Cypress-Gum Swamp (Blackwater Subtype) with dominant species including *Acer rubrum*, *Ilex* spp., *Liquidambar styraciflua*, *Lyonia lucidula*, *Morella cerifera*, *Nyssa* spp., *Persea palustris*, *Pinus* spp., *Quercus* spp., and *Taxodium distichum*. The forest was mature with 40-75% canopy cover. One female NLEB (CC2112) caught in net A on February 20, 2018 was fixed with transmitter 172.182.

ARNWR12 (35.80268, -75.93410) is in the east-central part of the refuge. The mist-net site was positioned behind gates that separated the maintained and unmaintained portions of Dry Ridge Road and Possum Road. Water-filled channels run parallel to the roads. The forest surrounding this site most closely resembled a Blackwater Bottomland Hardwoods (High Subtype) Forest transitioning into a Cypress-Gum Swamp (Blackwater Subtype) with dominant species including *Persea palustris*, *Pinus* spp., and *Taxodium distichum*. The forest was mature with greater than 75% canopy cover. Three NLEB were captured at this

site on 2 different nights: on February 21, 2018, 2 females were caught in net C (1 escaped before a band and transmitter could be placed and the other was tagged with band CC0723 and fixed with transmitter 172.124); and on February 22, 2018, 1 female (CC1056) caught in net D was fixed with transmitter 172.243.

Biological Sampling

On December 12, 2017, a total of 8 swab samples were sent to the SCWDS lab for *Pd* analysis. Results arrived via email on January 5, 2018 indicating that *Pd* was not detected by Polymerase Chain Reaction (PCR) in any of the submitted bat swabs. A formal laboratory report detailing the results of the 2017 analysis is included in Appendix H.

On April 16, 2018, a total of 28 swab samples were sent to Kennesaw State University for *Pd* analysis. Results have not been received at this time.

Copperhead was directed on December 20, 2017 to retain the guano samples for testing at a later date. NCDOT and USFWS instructed Copperhead on January 23, 2018 to not collect guano samples for the remainder of the project.

Discussion

The Fall 2017/Winter 2018 NCDOT NLEB Research Study successfully achieved its 4 goals. The capture of 17 NLEB during the project contributes to the growing body of evidence indicating that this species maintains a year-round presence in the Coastal Plain of North Carolina. The data gathered during this study also contribute to our knowledge of NLEB habitat preferences and roosting patterns in the study area and have begun to shed light on NLEB activity when weather is less than what is currently considered ideal for bat activity (i.e., <50°F; USFWS 2017).

While the habitat preferences of NLEB during the summer maternity season have been documented (Foster and Kurta 1999, Lacki and Schwierjohann 2001), winter habitat requirements for NLEB that do not use hibernacula are poorly known. It is likely that bats choose winter habitat according to its availability. Live and live damaged trees have been shown to buffer temperatures better than snags, retaining heat and desirable cavity temperatures longer at night (Coombs et al. 2010). In this study, as in previous results documented by Copperhead (2017), live and live-damaged *Nyssa aquatica/biflora* was the most common roost species used by NLEB. This tree species is also a dominate member in the non-riverine and gum-swamp natural communities sampled during this study. In general, the presence of cavities and crevices made these species more suitable for use by bats than those with exfoliating bark.

Bats were recorded as awake in fall and winter at lower than expected temperatures (37-38°F) based on the low-temperature cutoff for surveying guidelines (50°F; USFWS 2017). The longest torpor bouts recorded were 12-13 days. Speakman and Racey (1989) calculated that the longest a torpid bat can survive without water is 9-12 days and Boyles et al. (2006) suggest that many recorded winter roost switches may be linked to arousal from torpor to rehydrate. This could explain the recorded bat activity when temperatures

were less than ideal for insect availability. A better understanding of bat activity and ambient air temperature is hindered in part by the limitations of data loggers and in part by the mobility of bats. Frequently while a data logger was in place near a roost, bats emerged and flew out of range, selected a different roost, or shifted in a roost so the data logger could not pick up the transmitter signal enough to gather temperature data consistently. Though a lot of insightful data was recorded, the results only show a portion of a bat's overall heterothermic regime in the fall and winter.

No evidence of *Pd* infection has been found (thus far) from the biological swab samples. This may indicate that staying active during the fall and winter may make the Coastal Plain population less susceptible to the effects of *Pd*. More likely, it suggests that little or no overlap occurs with NLEB populations that hibernate in caves and mines farther to the west. The lack of suitable hibernacula in the region coupled with the current maximum known migration distance of 89 km (Griffin 1945) gives further evidence that the 2 populations may not mix. The lack of detectable *Pd* in the samples is a promising find for a disease as widespread and devastating to bat populations as WNS.

Continued *Pd* testing of fall and winter bat samples in the Coastal Plain of North Carolina is warranted. USGS (2017) documented that *Pd* is more readily detected in guano samples of active bats, suggesting guano sampling is a more reliable detection method for bats captured on the landscape in fall and winter.

Additional mist-netting will continue to shape a better understanding of the distribution, density, and habitat preferences of NLEB in the Coastal Plain. The use of temperature-sensitive transmitters adds to the overall knowledge of bat activity in the fall and winter but is also useful to document bat activity on nights with below-normal temperatures (i.e., when emergence counts are not being done because of the survey guidance temperature cut-off, or when bats remain in a roost for multiple days). Finally, the use of aerial foraging telemetry in future studies will help clarify how NLEB are using the survey area and how far they are traveling from their roost areas during the fall and winter.

Photo? or #	Ian	Ian	Ian	Ian	Ian	

Site Description, other than Habitat Info covered on pg 3:

Mixed forest with sand roads leading to Red Wolf Pens. Narrow fresh water ponds surrounded by clutter but open to bats where nets A, B, C were placed. Standing water in forest, around site. Liquidambar styraciflua, Pinus taeda, Quercus nigra, Morella cerifera, Magnolia virginiana, Symplocos tinctoria

Site sketch (label to match Nets/Traps above)

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Site Description, other than Habitat Info covered on pg 3:				<p>Site sketch (label to match Nets/Traps above)</p>														
Site located on Sand Ridge																		
and includes a road corridor																		
and a series of deep																		
freshwater ponds. The ridge																		
and pond are dominated by loblolly																		
pine and sweet gum. The																		
surrounding woods are a mosaic																		
of forested wetlands.																		

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Site sketch (label to match Nets/Traps above)

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

ARNWR1

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10–39% cover
- (3) medium, 40–75% cover
- (4) high, > 75% cover

Site Description, other than Habitat Info covered on pg 3:

Gravel road and trails leading through mixed wetland near edge of Milltail creek. Open water for bats to drink in stream channels. Surrounding forest is wetland. *Liquidambar styraciflua*, *Pinus taeda*, *Taxodium distichum*, *Morella cerifera*, *Acer rubrum*, *Magnolia virginiana*, *Symplocos tinctoria*

Site sketch (label to match Nets/Traps above)

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

ARNWR5

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land) / mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10–39% cover

(3) medium, 40–75% cover

(4) high, > 75% cover

Site Description, other than Habitat Info covered on pg 3:													
Gravel road with low maintenance													
Side road dead ending in a mixed forest open water for bats to drink from in channels and road cuts.													
Surrounding forest is wetland. Pinus taeda.													
Persea palustris, Chamaecyparis thyoides													
*swamp bay, Atlantic white cedar													

Site sketch (label to match Nets/Traps above)

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10–39% cover
- (3) medium, 40–75% cover
- (4) high, > 75% cover

Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10-39% cover

(3) medium, 40-75% cover

(4) high, > 75% cover

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

ARNWR12

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / (mixed) / unforested

Upland / (bottomland)

(Managed) (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

(Natural) (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10–39% cover
- (3) medium, 40–75% cover
- (4) high, > 75% cover

GRO1

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood (mixed) / unforested

Upland (bottomland)

Managed (thinned, burned, pine plantation or otherwise disturbed) / (unmanaged)

(Mature forest) / <20 years old forest or cutover

(Natural) (>50% wooded), rural (>50% agricultural land) / mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Mist Net Sites Habitat Info – please **circle** the option that best fits

GR2

Pine / hardwood / mixed / unforested

Upland / (bottomland)

Managed (thinned, burned, pine plantation or otherwise disturbed) / (unmanaged)

(Mature forest) / <20 years old forest or cutover

(Natural (>50% wooded)) / rural (>50% agricultural land) / mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10-39% cover

(3) medium, 40-75% cover

(4) high, > 75% cover

*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For **mist net sites**, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info – please **circle** the option that best fits

GRO4

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

PHASE 4 EMERGENCE SURVEYS

Site Name/#: ARNWR 2 Roost Name/#: 422

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	1	

* If any bats return to the roost during the survey, then they should be subtracted from the tally.

Describe Emergence: Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

Bat emerged at 1742. It was too dark to see it emerge.
Heard it leave with a receiver.

APPENDIX E
PHASE 4 EMERGENCE SURVEYS

Site Name/ #: ARNWR 1 Roost Name/ #: 762

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:		

* If any bats return to the roost during the survey, then they should be subtracted from the tally.

Describe Emergence: Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

Bat did not leave roost until 1751. It was too dark to see bat emerge. Heard it leave with receiver.

Cavity

Notes RT is part of
split-trunk tree

A 10 factor English prism is used to identify trees within the plot, centered on the roost tree

1 Ownership: Private; Federal; State; City; Other; Unknown

2 Decay State: 1 Live; 2 Declining; 3 Dead; 4 Loose Bark; 5 Clean; 6 Broken; 7 Decomposed; 8 Down Material; 9 Stump (See Back for Reference)

3 Tree Ranking: Canopy; Sub-Canopy; Understory

4 Roost Type: Tree-Live; Tree-Dead; Bat Box-Standard; Bat Box-Rocket; Bat Box-Condo; Artificial Bark; Utility Pole; Private Residence; Public Building; Auxiliary Structure-barn/shed; Other Occupied Structure; Other Unoccupied Structure; Cave; Mine; Talus Slope; Rock Outcrop; Unknown

5 MicroHabitat: Exfoliating Bark; Cavity; Crevice/Crack; Canopy/Cluster of Leaves; Other

Roost No. 984

Bat Species/Sex/Frequency: MYSE/F/.124

Band # CC1453

APPENDIX E
PHASE 4 EMERGENCE SURVEYS

Site Name/#: ARNWR Roost Name/#: 984

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	0	

* If any bats return to the roost during the survey, then they should be subtracted from the tally.

Describe Emergence: Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

Unsuccessful, no bats emerged.

Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:		

* If any bats return to the roost during the survey, then they should be subtracted from the tally.

Describe Emergence: Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

One bat (radio-tagged) emerged & left the area immediately

APPENDIX E
PHASE 4 EMERGENCE SURVEYS

USFWS BAT EMERGENCE SURVEY DATASHEET

Date: 11-29-2017 Surveyor(s) Full Name: Theresa Wetzel, Meghan Raley
 State: NC County: Dare Project Name: Eastern NC UMYSE
 Site Name/#: ARNWP-1 Roost Name/# 433 Bat #: CC1691
 Lat/Long or UTM of Roost: 35.82608/-75.90624
 Description of Roost/Habitat Feature Surveyed: live tree, cavity

Bat Species Known to be using this Roost/Feature (if not known, leave blank):
Myotis septentrionalis

Other Suspected Bat Species (explain): none

Weather Conditions during Survey (temperature, precipitation, wind speed):
53, clear, calm

Survey Start Time: 1630 Time of Sunset: 1650 Survey End Time: 1750

NOTE: Emergence surveys should begin ½ hour before sunset and continue until at least one hour after sunset or until it is otherwise too dark to see emerging bats. The surveyor(s) should position him or herself so that emerging bats will be silhouetted against the sky as they exit the roost. Tallies of emerging bats should be recorded every few minutes or as natural breaks in bat activity allow. Please ensure that surveyor(s) are close enough to the roost to observe all exiting/returning bats, but not close enough to influence emergence (i.e., do not stand directly beneath the roost and do not make unnecessary noise and/or conversation, and minimize use of lights other than a small flashlight to record data, if necessary). Do not shine a light on the roost tree crevice/cave/mine entrance itself as this may prevent or delay bats from emerging. If available, use of an infra-red, night vision, or thermal-imaging video camera or spotting scope and an ultrasonic bat detector are strongly recommended but not required.

Time	Number of Bats Leaving Roost*	Comments / Notes
1725	1	did not see bat emerge, confirmed emergence w/ telemetry equip.
		tagged bat 172.783

APPENDIX E
PHASE 4 EMERGENCE SURVEYS

Site Name/#: ARUWR5 Roost Name/#: 432

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	1	

* If any bats return to the roost during the survey, then they should be subtracted from the tally.

Describe Emergence: Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

Radio-tagged bat (.722) emerged at 1733, and left the
dred around tree 432 immediately. No other bats were
sighted.

Interior	Edge	Open

% Canopy Closure

Roost Type⁴

MicroHabitat⁵ Used by Bat

Notes _____

A 10 factor English prism is used to identify trees within the plot, centered on the roost tree

- 1 **Ownership:** Private; Federal; State; City; Other; Unknown
- 2 **Decay State:** 1 Live; 2 Declining; 3 Dead; 4 Loose Bark; 5 Clean; 6 Broken; 7 Decomposed; 8 Down Material; 9 Stump (See Back for Reference)
- 3 **Tree Ranking:** Canopy; Sub-Canopy; Understory
- 4 **Roost Type:** Tree-Live; Tree-Dead; Bat Box-Standard; Bat Box-Rocket; Bat Box-Condo; Artificial Bark; Utility Pole; Private Residence; Public Building; Auxiliary Structure-barn/shed; Other Occupied Structure; Other Unoccupied Structure; Cave; Mine; Talus Slope; Rock Outcrop; Unknown
- 5 **MicroHabitat:** Exfoliating Bark; Cavity; Crevice/Crack; Canopy/Cluster of Leaves; Other
