## 1.0 PROJECT DESCRIPTION

The North Carolina Department of Transportation (NCDOT) requested Ecological Engineering, LLP and its subcontractor Ecological Solutions, Inc. (project team) to assist in conducting portions of a research study of the northern long-eared bat (*Myotis septentrionalis*, NLEB, or MYSE) in eastern North Carolina. Mist-net surveys were conducted in three counties (Carteret, Craven, and Jones) within the Croatan National Forest (Croatan NF) for two sessions (fall 2017 and winter 2018). The objectives of the study are as follows:

- Determine the distribution of NLEB in eastern North Carolina, further document fall/winter activity, and develop greater understanding of NLEB winter habitat use and behavior;
- Conduct mist-netting and radio telemetry on NLEBs to locate and characterize day roost in late fall/winter;
- Swab susceptible bats to determine presence/absence of *Pseudogymnoascus destructans* (Pd), the fungus that causes white nose syndrome (WNS).

This report includes results of two mist-net survey sessions (1 & 2) and tracking which occurred from November 15<sup>th</sup>, 2017, to March 21<sup>st</sup>, 2018, in Carteret, Craven, and Jones Counties within the Croatan NF (Figures 1 & 2). Session 1 mist-net surveys occurred late fall of 2017 from November 15<sup>th</sup> to December 20<sup>th</sup>, and Session 2 mist-net surveys were conducted during the winter of 2018 from December 27<sup>th</sup> to February 28<sup>th</sup>. Other than a two day break from December 24<sup>th</sup> to 25<sup>th</sup>, 2017, tracking continued throughout the survey period from December 3<sup>rd</sup> to March 21<sup>st</sup>.

During Session 1, fall 2017, the project team conducted mist-net surveys in a total of 14 locations, including the site of a 2017 NC Wildlife Resources Commission (NCWRC) NLEB capture in Craven County (Figures 3 & 4 a-b). During Session 2, winter 2018, the project team conducted mist-net surveys in a total of 17 locations (Figures 5 a-b). The counties surveyed and site numbers are listed below. Detailed site descriptions, conditions, and survey dates can be found in Tables 1-6.

Session 1, fall 2017:

1. Carteret County a total of two locations (Sites 1 and 2)
2. Craven County a total of five locations (Sites 1-5)
3. Jones County a total of seven locations (Sites 1-7)

Session 2, winter 2018

1. Carteret County a total of two locations (Sites 2 & 3)
2. Craven County a total of nine locations (Sites 1, 3, 4, and 6-11)
3. Jones County a total of six locations (Sites 1-4, 8, and 9)

All surveys were conducted within suitable roosting and foraging habitat for NLEB and were conducted by qualified bat biologists currently permitted by the US Fish and Wildlife Service (USFWS) and NCWRC. Special use permits were obtained from the Croatan NF and Weyerhaeuser Company. Mist-netting at the above-referenced project locations was conducted with the goal of catching NLEB. All captured NLEB were fitted with transmitters, and telemetry was utilized to find roost locations. Emergence counts were performed following USFWS protocols at roost locations when weather conditions allowed.

## 2.0 QUALIFICATIONS

Ecological Engineering staff provided project administration, coordination, quality assurance, field support, and deliverable preparation on this contract.

Lane Sauls served as contract manager and assisted with coordination for this project. Lane's experience includes 23 years working in the natural resources field as project scientist, project manager, and contract manager for numerous projects across North Carolina.

Project manager David Cooper assisted with habitat characterization, report preparation, and quality assurance. David has 19 years of work experience in the natural resources field, including three years of experience assisting with bat surveys.

Ecological Engineering contracted with Ecological Solutions to perform field surveys and data analysis. All surveys were conducted by qualified biologists authorized to perform bat surveys under applicable USFWS and NCWRC permits.

The Ecological Solutions survey team was led by Senior Ecologist Dottie Brown and Bat Ecologist Kristi Confortin.

Dottie Brown served as principal investigator on this project. She was the lead biologist for site selection, mist-net, radio tracking, roost and emergence surveys. Dottie also oversaw data analysis and assisted with report writing for this project. Dottie holds a Federal USFWS Section 10 permit (TE94704A-1) as well as a NCWRC (18-ES00367) Scientific Collection permit. She has 11 years of experience performing bat surveys in the southeastern United States, Central America, and Africa, utilizing techniques such as pit tagging, emergence surveys, acoustic surveys, harp traps and mist-nets, radio telemetry, roost surveys, and hibernacula surveys.

Kristi Confortin served as a permitted biologist on mist-net surveys, radio tracking, and roost and emergence surveys and assisted with data and report preparation. Kristi is covered under the Ecological Solutions Federal USFWS Section 10 permit (TE48579B-2) and the NCWRC (18-ES00141). Kristi has five years of natural resource experience including bat mist-netting, banding, acoustics, and radio telemetry, and roost and hibernacula surveys.

## 3.0 METHODOLOGY

This section describes the methods used to perform mist-net surveys. Survey methodology followed procedures and protocols set forth by the NCDOT project scope dated October 9<sup>th</sup>, 2017 and the USFWS 2017 Range-Wide Indiana Bat Summer Survey Guidelines (USFWS 2017). All surveys adhered to the protocols stipulated in the USFWS National White Nose Syndrome Decontamination Protocol (USFWS 2016), North Carolina's White-nose Syndrome Surveillance and Response Plan (NCWRC 2016), and North Carolina Department of Transportation Decontamination Protocol (NCDOT 2017). Due to previous coordination, USFWS did not require site-specific survey plans.

### 3.1 Mist-net Surveys

Mist-net surveys were performed with the goal of capturing NLEB in three counties (Carteret, Craven, and Jones) within the Croatan NF. The most suitable mist-net sites were selected by permitted bat ecologist Dottie Brown. Net deployments were individually tailored to specific available habitats and

flight corridors, and configurations utilized combinations of nets sized between four and twelve meters in length, single or stacked between one net panel and three net panels in height. Between four and nine net sets were deployed at each survey site per calendar night of mist-net surveys. Each mist-net site was photographed, and a GPS point was taken. Figures 4 a-b, and 5 a-b depict the locations of mist-net sites within each of the three counties sampled. At the onset of the research in November 2017, mist-netting was only conducted on nights for which the forecast temperature was greater than 50° Fahrenheit (F) at the beginning of each nightly survey period. In addition, surveys were completed for 5 hours unless the temperatures dropped below 45° F; however, during Session 1 in late November NCDOT and USFWS approved continuing surveys until temperatures dropped to 40° F. Lascar Electronics model EL-USB-1-LCD temperature data loggers provided by NCDOT were deployed at each site to assist in documenting temperatures at the time of each bat capture. NCDOT mist-net data sheets, which also require documentation of all information contained in the USFWS Sample Data Sheet for Indiana Bat Surveys (USFWS 2017), were used to record mist-net site and capture data.

### 3.2 Radio Tracking

During the 2017 fall Session, two NLEB were captured in Craven County (Figures 6 and 6a), and three NLEB were captured during the 2018 winter session in Carteret and Craven Counties (Figures 7 and 7a) for a total of five NLEB captured within the Croatan NF. All five NLEB were fitted with 21-day Holohill Systems, LB – 2x radio transmitters within the 150-frequency range. Transmitter attachment adhered to methodology described in the 2017 Range-wide Indiana Bat Summer Survey Guidelines (USFWS 2017). Bats were tracked daily until the roost was located or for a maximum of eight hours. Radio tracking was performed primarily by pedestrian means using a handheld three or five-element antenna. In the event a transmitter signal was lost, methods used to relocate the signal included expanded pedestrian transects and vehicular transects using an elevated, pole-mounted five-element antenna. During the course of radio tracking, field conditions (i.e. flooding and prescribed fire) prevented roost documentation for a total of six days. Radio tracking efforts continued for NLEBs 302 and 180 for the entire 21-day period. Radio tracking efforts continued for NLEB 430 for 16 days until the dropped transmitter was located on the 16<sup>th</sup> day, and for NLEB 100 for five days until the dropped transmitter was located on the fifth day.

NLEB 340 was tracked from December 19<sup>th</sup>, 2017 to January 10<sup>th</sup>, 2018 for a total of 21 days with a two day break on December 24<sup>th</sup> and 25<sup>th</sup> during which no tracking was conducted. After the 21-day tracking period, NCDOT and USFWS approved a continuation of tracking for this bat until the transmitter signal died; therefore, tracking continued another nine days until January 19<sup>th</sup>. After transmitter failure, NLEB 340 was able to be visually observed in its roost tree (340D), and surveyors, on a volunteer basis, continued checking the roost tree daily for visual documentation of NLEB 340 for another 16 days outside of the scope of this project and with NCDOT approval, until February 13, 2018.

### 3.3 Roost Inspection/Emergence Surveys

Roost documentation was conducted utilizing the USFWS Emergence Survey Datasheet (USFWS 2017). Each roost was photographed, and a GPS point was taken. Figures 8a and 9a-b depict the locations of roosts documented during each session. Emergence counts were performed at each roost within the parameters of the scope to include:

- The scoped emergence count duration was from one half hour before dusk to one hour after dusk.
- Bats exiting the roost were counted in five minute intervals.

- Temperatures were recorded at the beginning and end of each emergence count.
- Emergence counts were not performed at every roost for every bat due to temperatures below 45°F, rain, high winds, or heavy fog.

### 3.4 Habitat Characterization

Prior to performing field surveys, a desktop Geographic Information System (GIS) assessment using the most recent available color aerials of the study area was performed to determine availability of potentially suitable habitat for NLEB. This information was utilized to guide preliminary site selection. A pre-netting site visit was conducted between November 6<sup>th</sup> and 8<sup>th</sup>, 2017, to verify the presence of suitable habitat and finalize mist-net site locations. Field assessments included extensive pedestrian reconnaissance of the study area (Croatan NF).

Habitat at each mist-net site was described by community type as described in *The Guide to the Natural Communities of North Carolina, Third Approximation* (Schafale, 1990). In addition, each mist-net site's habitat was scored as either:

- 1) pine/hardwood/mixed/unforested;
- 2) upland/bottomland;
- 3) managed (thinned, burned, or pine plantation)/unmanaged;
- 4) mature forest/ <20 years old forest or cutover;
- 5) natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural):
- 6) clutter estimate as either,
  - (1) sparse/no, <10% cover;
  - (2) low, 10-39% cover;
  - (3) medium, 40-75% cover;
  - (4) high, >75% cover

For each documented NLEB roost, a USFWS Indiana Bat Roost data sheet was completed and habitat was characterized by community type as described in *The Guide to the Natural Communities of North Carolina, Third Approximation* (Schafale, 1990).

## 4.0 FINDINGS

This section describes the results of habitat assessments, mist-net surveys and captures, tracking efforts, and roost documentation and emergence surveys during Session 1 fall (November 15<sup>th</sup> to December 20<sup>th</sup>, 2017) and Session 2 winter (December 27<sup>th</sup>, 2017 to March 21<sup>st</sup>, 2018).

### 4.1 Mist-net Sites and Habitat Descriptions

The mist-net sites monitored were chosen based on the availability of suitable habitat for northern long-eared bats, proximity to foraging areas, and flight corridors. During Session 1 fall 2017, mist-net surveys were conducted at 2 locations in Carteret County, 5 locations in Craven County, and 7 locations in Jones County for a total of 42 crew nights. During Session 2 winter 2018, mist-net surveys were conducted at 2 locations in Carteret County, 9 locations in Craven County, and 6 locations in Jones County for a total of 47 crew nights. On average 4-9 nets were deployed per night. Mist-net sites are described below. Additional mist-net site data and dates sampled are presented in Tables 1 through 6. Please refer to Figures 4 a-b and 5 a-b accompanying this report for the locations of mist-net sites.

#### 4.1.1 – Carteret County

**Mist-net Site 1-Carteret** is located in the southeastern portion of the forest along Forest Service (FS) Road 183 just off FS Road 181/Oyster Point at approximately 34.761987°, -76.762163°. The mist-net site was situated in upland, mesic, mixed pine and hardwood forest at the edge of an upland row pine/managed pine stand. This community type consists of a canopy of longleaf pine (*Pinus palustris*), loblolly pine (*Pinus taeda*), sweetgum (*Liquidambar styraciflua*), live oak (*Quercus virginiana*), and water oak (*Quercus nigra*). The understory is partially open and consists of wax myrtle (*Morella cerifera*), fetterbush (*Lyonia lucida*), swamp bay (*Persea palustris*), flowering dogwood (*Cornus florida*), American holly (*Ilex opaca*), large gallberry (*Ilex coriacea*), and greenbrier (*Smilax* sp.). Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) (Schafale, 1990), Coastal Plain Small Stream Swamp (Blackwater Subtype), (Schafale, 1990) and managed pine.

**Mist-net Site 2-Carteret** is located in the eastern portion of the forest. The mist-net site was located along Millis Swamp Road/FS Road 177 at approximately 34.77828°, -76.96162°. Nets were situated along FS Road 177 where the road intersects with Juniper Branch, surrounded by upland row/managed loblolly pine and longleaf pine. This community type consists of a canopy of loblolly pine, longleaf pine, sweetgum, water oak, swamp tupelo (*Nyssa biflora*), sweet bay magnolia (*Magnolia virginiana*), American holly, red maple (*Acer rubrum*), Atlantic white-cedar (*Chamaecyparis thyoides*), laurel oak (*Quercus hemisphaerica*), and swamp titi (*Cyrilla racemiflora*). The understory contains species typical of peatland communities, such as fetterbush, large gallberry, wax myrtle, and giant cane (*Arundinaria gigantea*), and greenbrier. Community types in proximity to the mist-net site include Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 3-Carteret** is located in the southeastern portion of the forest along Millis Road (FS Road 128) at approximately 34.76831°, -76.97234°. This area consists of an upland and bottomland mix, with managed row pine stands and riparian hardwood forest. The mist-net site was situated along Millis Road/FS Road 128 at its intersection with a small stream and swamp complex. This community type consists of a canopy of loblolly pine, sweetgum, bald cypress (*Taxodium distichum*), swamp tupelo, sweet bay magnolia, and American holly. The understory contains species typical of peatland communities, such as fetterbush, large gallberry, wax myrtle, and giant cane. Community types in proximity to the mist-net site include Coastal Plain Small Stream Swamp (Blackwater Subtype).

#### 4.1.2 – Craven County

**Mist-net Site 1-Craven** is located in the northeastern portion of the forest at a NCWRC game land located off of Mill Branch Road/FS Road 170 at approximately 34.027270°, -77.046536°. The mist-net site was situated where a forest road intersects with two unnamed tributaries to Brice Creek and a wetland/swamp. The immediate area surrounding the site consists of a canopy dominated by sweetgum, flowering dogwood, swamp bay, red maple, tulip poplar (*Liriodendron tulipifera*), swamp chestnut oak (*Quercus michauxii*), black willow (*Salix nigra*), water tupelo (*Nyssa aquatica*), overcup oak (*Quercus lyrata*), white oak (*Quercus alba*), southern red oak (*Quercus falcata*), and turkey oak (*Quercus laevis*). The understory is mostly open, and contains giant cane, American holly, wax myrtle, dog hobble (*Leucothoe axillaris*), netted chain fern (*Woodwardia areolata*), horse sugar (*Symplocos tinctoria*), and inkberry (*Ilex glabra*). Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal

Plain Subtype), Coastal Plain Semipermanent Impoundment (Schafale, 1990), and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 2-Craven** is located in the northeastern portion of the forest, along Mill Branch Road/FS Road 170 where it intersects Black Branch at approximately 35.01611°, -77.05026°. The mist-net site was situated within an upland mixed hardwood forest and along the edge of a large cypress-gum swamp/pond. The immediate area surrounding the site consists of a canopy dominated by water oak, white oak, loblolly pine, sweetgum, sweet bay magnolia, swamp chestnut oak, eastern red cedar (*Juniperus virginiana*), and the cypress-gum swamp/pond contains bald cypress, swamp tupelo (*Nyssa biflora*), and black willow. The understory is moderately dense, and contains swamp bay, wax myrtle, fetterbush, inkberry, giant cane, American holly, horse sugar, highbush blueberry (*Vaccinium corymbosum*), and lanceleaf greenbrier (*Smilax smallii*). Vines are common, and include Carolina jasmine (*Gelsemium sempervirens*) and roundleaf greenbrier (*Smilax rotundifolia*). Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype), Coastal Plain Semipermanent Impoundment, and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 3-Craven** is located in the northeastern portion of the forest at approximately 35.04836°, -77.05100°. The mist-net site was situated between a wetland and cypress-gum swamp/pond, along a gated forest road that connects with FS Road 121-A and Brice Creek boat ramp. The surrounding forest canopy consists of loblolly pine, sweetgum, water oak, flowering dogwood, white oak, turkey oak, swamp chestnut oak, tulip poplar, swamp bay, overcup oak, sourwood (*Oxydendrum arboreum*), northern red oak (*Quercus rubra*), American beech (*Fagus grandifolia*), and scarlet oak (*Quercus coccinea*), and the wetland and cypress-gum swamp/pond canopy consist of gum/tupelo and bald cypress. The upland understory is relatively sparse, and contains American holly, giant cane, horse sugar, dwarf palmetto (*Sabal minor*), and Christmas fern (*Polystichum acrostichoides*). Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype), Coastal Plain Semipermanent Impoundment, and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 4-Craven** is located in the middle of the forest along FS Road 178 off of Middle Little Road/FS Road 121-2 at approximately 35.00707°, -77.07463°. The mist-net site was situated between a creek/swamp and is surrounded by mixed pine and hardwood forest. The canopy consists of loblolly pine, red maple, sweetgum, water oak, black gum, bald cypress, swamp bay, turkey oak, and mimosa (*Albizia julibrissin*). A dense understory includes American holly, wax myrtle, dog hobble, giant cane, swamp bay, fetterbush, cinnamon fern (*Osmundastrum cinnamomeum*), Carolina jasmine, and several species of greenbrier. Community types in proximity to the mist-net site include Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 5-Craven** is located in the middle of the forest along FS Road 202 off of Middle Little Road/FS Road 121-2 at approximately 34.96789°, -77.05271°. The mist-net site was situated at the edge of a large wetland and several tributary streams to West Prong Brice Creek and a managed pine stand. The canopy consists of red maple, bald cypress, water tupelo, sweetgum, loblolly pine, longleaf pine, white oak, turkey oak, dogwood, and pond pine (*Pinus serotina*). The understory consists of swamp bay, American holly, inkberry, wax myrtle, fetterbush, and dog hobble. Community types in proximity to the mist-net site include Mesic

Mixed Hardwoods (Coastal Plain Subtype) and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 6-Craven** is located in the northern portion of the forest adjacent of the NCWRC Wildlife Management Area (WMA) just off of forest service road 121A at approximately 35.044312°, -77.068239°. The mist-net site was located within both an upland mesic mixed hardwoods and blackwater stream and swamp. The immediate area surrounding the site consists of a canopy dominated by sweetgum, loblolly pine, bald cypress, red maple, white oak and southern red oak. The understory is sparse, and contains swamp and red bay, giant cane, highbush blueberry, and fetterbush. Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 7-Craven** is located within a NCWRC WMA along North Little Road/FS Road 121-1 at approximately 35.040608°, -77.066028° in the northern portion of the forest approximately 1.20 miles from Brice Creek. The mist-net site was situated within an upland mixed hardwood and pine forest with a canopy that is dominated by white oak, southern red oak, sweetgum, loblolly pine, sourwood, and dogwood. The adjacent wetland and bottomland canopy consist of bald cypress, water and swamp tupelo, red maple, and swamp bay. The relatively sparse understory includes hardwood saplings including white oak, southern red oak, sourwood and sweetgum as well as dog hobble, fetterbush, wax myrtle, high bush blueberry, and smilax spp. Community types in proximity to the mist-net site include Dry-Mesic Oak-Hickory Forest (Coastal Plain Subtype) (Schafale, 1990) and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 8-Craven** is located in the northeastern portion of the forest along Hope Road/FS Road 3046 at approximately 34.92144°, -76.83989°. The mist-net site was situated along a wide forest road that intersects with a large pond and wetland surrounded by an upland mature mixed pine and hardwood forest. The canopy in the upland habitat includes loblolly pine, white oak, sweetgum, southern red oak, water oak, live oak, and sourwood, and the adjacent wetland canopy includes bald cypress, red maple, and water tupelo. The understory and herbaceous layers include American holly, highbush blueberry, doghobble, roundleaf greenbrier, lanceleaf greenbrier, saw greenbrier, and grape vines (*Vitis* sp.). Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype), Coastal Plain Semipermanent Impoundment, and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 9-Craven** is located in the northeastern portion of the forest where Hope Road/FS Road 3046 and the Neusiok National Recreation Trail intersect at approximately 34.91064°, -76.81831°. The mist-net site was situated in a wetland associated with Still Gut Creek and is surrounded by a mature mixed pine and hardwood forest. The canopy consists of loblolly pine, sweetgum, southern red oak, eastern red cedar, and sweet bay magnolia. The understory is open and consists of fetterbush, giant cane, and greenbrier. Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) and Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Mist-net Site 10-Craven** is located in the center of the forest along Hunters Creek Road/FS Road 144 at approximately 34.80819°, -77.07938°. The mist-net site was situated along Hunters Creek Road where it intersects with Wolf Swamp surrounded by an upland, mesic, mixed pine and hardwood forest and a managed pine stand. The upland managed row/pine stand canopy

consists of longleaf pine and loblolly pine, and mesic mixed pine and hardwood canopy consists of water oak, laurel oak, sweetgum, white oak, and southern red oak. The mist-nets were established within the riparian corridor of Wolf Swamp where the canopy consists of bald cypress, red bay, swamp bay, water oak, sweetgum, dogwood, water tupelo and swamp tupelo. The understory and herbaceous layers are partially open and consist of American holly, giant cane, fetterbush, dog hobble, inkberry, and greenbrier. Community types in proximity to the mist-net site include Coastal Plain Small Stream Swamp (Blackwater Subtype). It should be noted that a discrepancy in the location of the Craven/Carteret county line between the U.S. Forest Service (USFS) map and the NCDOT GIS shapefile exists in this vicinity. For the purposes of this report, we have utilized the USFS line, but show both lines on the attached mapping.

**Mist-net Site 11-Craven** is located in the northwestern portion of the forest along Middle Little Road/FS Road 121-2 where it intersects with West Prong Brice Creek at approximately 34.97012°, -77.04887°. The mist-net site was situated in a small blackwater stream and swamp habitat surrounded by upland row pine/managed pine stands. This community type consists of a canopy of longleaf and loblolly pine, sweetgum, bald cypress, red maple, dogwood, American hop-hornbeam (*Ostrya virginiana*), sugar maple (*Acer saccharum*), and swamp chestnut oak. The understory is partially open and consists of American holly, wax myrtle, swamp and red bay, and greenbrier. Community types in proximity to the mist-net site include Coastal Plain Small Stream Swamp (Blackwater Subtype).

#### **4.1.3 – Jones County**

**Mist-net Site 1-Jones** is located in the western portion of the forest at the Dixon Field Boat Ramp along the White Oak River at approximately 34.85598°, -77.21021°. The mist-net site was along FS Road 3057 and is situated within a mesic mixed pine and hardwood forest. The community type consists of a canopy of water oak, loblolly pine, sweetgum, swamp bay, tulip poplar, American beech, swamp chestnut oak, American holly, and sourwood. The understory is open and consists of giant cane, swamp bay, and cat greenbrier (*Smilax glauca*). Community types in proximity to the mist-net site include Coastal Plain Bottomland Hardwoods (Blackwater Subtype) (Schafale, 1990) and Mesic Mixed Hardwoods, Coastal Plain Subtype.

**Mist-net Site 2-Jones** is located in the western portion of the forest within a mesic mixed pine and hardwood forest associated with Black Swamp Creek and approximately 1.12 miles from the White Oak River at approximately 34.87309°, -77.20116°. The mist-net site was situated at the edge of an NCWRC WMA with a surrounding forest consisting of moderately dense loblolly pine, sweetgum, and red maple. The understory is moderately dense, and includes giant cane, highbush blueberry, and sapling hardwoods including sweetgum, loblolly pine, and red maple. Vines include roundleaf and lanceleaf greenbrier, and Japanese honeysuckle (*Lonicera japonica*). Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) and managed herbaceous areas.

**Mist-net Site 3-Jones** is located in the southwestern portion of the forest along Haywood, Landing Road/FS Road 146 at approximately 34.81921°, -77.18228°. The mist-net site was located just off of the White Oak River where mist-nets were situated at the edge of large wetland surrounded by a mature, mesic, mixed pine and hardwood forest. The canopy consisted of white oak, sweetgum, northern red oak, American beech, loblolly pine, water oak, tulip poplar, and pignut hickory (*Carya glabra*). The understory is open in the upland mixed pine and hardwood forest in vicinity of the mist-nets and included giant cane and smilax species.

Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) and Tidal Cypress-Gum Swamp (Schafale, 1990).

**Mist-net Site 4-Jones** is located in the northwestern portion of the forest just east of U.S. Route 17 (US 17) along Crooked Run Road at approximately 34.946018°, -77.233817°. The mist-net site was situated at the edge of a mesic mixed pine and hardwood forest and a blackwater stream and swamp habitat where the canopy consisted of sweetgum, loblolly pine, red maple, southern red oak, water oak, live oak, laurel oak, American beech, white oak, tulip poplar, pignut hickory, and northern red oak. A cluttered understory and herbaceous layer included wax myrtle, swamp bay, American holly, dog hobble, giant cane, high bush blueberry, wild grape vine, Carolina jasmine, horse sugar, occasional dwarf palmetto and greenbrier. Community types in proximity to the mist-net site include Nonriverine Wet Hardwood Forest (Schafale, 1990).

**Mist-net Site 5-Jones** is located in the northwestern portion of the forest at approximately 34.917830°, -77.231235° along a forest road that runs parallel to US 17. The mist-net site was within a swamp habitat with a mixed mature pine and hardwood forest. Tree species appearing in the canopy include loblolly pine, red maple, sweetgum, black gum, water oak, and water tupelo. The understory was open with a sparse herbaceous layer to include swamp bay, American holly, highbush blueberry, fetterbush, horse sugar, Carolina jasmine, doghobble, and occasional dwarf palmetto. Vines are common, and include roundleaf greenbrier, and laurel-leaf greenbrier (*Smilax laurifolia*). Community types in proximity to the mist-net site include Nonriverine Wet Hardwood Forest.

**Mist-net Site 6-Jones** is located in the northwestern portion of the forest along a forest road that runs that parallels US 17 at approximately 34.92310°, -77.23143°. The mist-net site was within a swamp habitat within a mixed mature pine and hardwood forest. Tree species appearing in the canopy include red maple, sweetgum, swamp chestnut oak, black gum, and water oak. A sparse and open understory included swamp bay, American holly, highbush blueberry, fetterbush, horse sugar, Carolina jasmine, doghobble, and occasional dwarf palmetto. Vines are common, and include roundleaf greenbrier, and laurel-leaf greenbrier. Community types in proximity to the mist-net site include Nonriverine Wet Hardwood Forest.

**Mist-net Site 7-Jones** is located in the western portion of the forest south of Catfish Lake and along Mirey Branch Road/FS Road 172 just off of Catfish Lake Road at approximately 34.88871°, -77.16588°. The mist-net site was situated in a blackwater stream swamp habitat with both upland mixed pine and hardwood forest and at the edge of an upland row pine/managed pine stand. This community type consists of a canopy of loblolly pine, sweetgum, swamp chestnut oak, white oak, black gum, red maple, and water oak. The understory is cluttered and consists of hardwood saplings including sweetgum, red maple, wax myrtle, fetterbush, swamp bay, giant cane, large gallberry, and greenbrier. Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) and Tidal Cypress-Gum Swamp.

**Mist-net Site 8-Jones** is located in the northwestern portion of the forest just east of US 17 along Crooked Run Road and west of Weyerhaeuser property at approximately 34.94943°, -77.21955°. The mist-net site was situated at the edge of a mesic mixed pine and hardwood forest bordering a mesic row pine / managed stand. The canopy consisted of sweetgum, loblolly pine, red maple, southern red oak, water oak, live oak, white oak, tulip poplar, pignut hickory, and northern red oak. A cluttered understory and herbaceous layer included wax myrtle, swamp

bay, American holly, dog hobble, giant cane, highbush blueberry, grape vine, Carolina jasmine, horse sugar, occasional dwarf palmetto and greenbrier. Community types in proximity to the mist-net site include Mesic Mixed Hardwoods (Coastal Plain Subtype) and Nonriverine Wet Hardwood Forest.

**Mist-net Site 9-Jones** is located in the western portion of the forest along Holston Creek Road where FS Road 134 and 203 intersect at approximately 34.84672°, -77.13167°. The mist-net site was situated along Holston Creek in a blackwater stream swamp habitat with both upland mixed pine and hardwood forest and at the edge of an upland row pine/managed pine stand. This community type consists of a canopy of loblolly pine, sweetgum, tulip poplar, white oak, red maple, and water oak. The understory is partially open and consists of red and swamp bay, American holly, dwarf palmetto, wax myrtle, doghobble, fetterbush, swamp bay, giant cane, large gallberry, Japanese honeysuckle, grape vine, and greenbrier. Community types in proximity to the mist-net site include Coastal Plain Small Stream Swamp (Blackwater Subtype).

**Table 1 - Mist-net Site Summary 2017 – Croatan National Forest within Carteret County**

Site	Lat, Long	Community Type (per Schafale 1990 unless otherwise noted)	Dates	Start, End Times	Survey Hours	Weather Conditions
1-Carteret	34.761987°, -76.762163°	Upland Managed Pine (not a natural community), and Mesic Mixed Hardwoods, (Coastal Plain Subtype) and Coastal Plain Small Stream Swamp, (Blackwater subtype)	12/12/2017	16:30, 20:10	3.40	Clear, light wind to none, 57°-44° F
2- Carteret	34.77828°, -76.96162°	Coastal Plain Small Stream Swamp, (Blackwater Subtype)	12/12/2017	16:43, 20:09	3.26	Partly cloudy to clear, light wind to none, 51.5°-36° F
			12/15/2017	16:28, 21:40	4.38	Cloudy, no wind to light wind, 53°-42° F
			12/17/2017	16:42, 22:26	5.28	Cloudy, no wind, 51°-47° F

## 4.2 NLEB Capture Site Habitat Descriptions

Five NLEB were captured in Carteret and Craven Counties. NCDOT, USFWS and state agencies were notified within 24 hours of a capture in accordance with the requirements of all federal and state permits. Copies of capture notifications can be found in Appendix H. All *Myotis* species were photographed, and temperatures at the time of capture were documented. All NLEB capture sites are described below. Additional mist-net capture data are presented in Tables 7 - 9. Please refer to the Figures accompanying this report for the locations of mist-net sites.

### 4.2.1 – Croatan National Forest Carteret County

**Mist-net Site 2-Carteret** is the site of a male NLEB captured on 2/20/2018, transmitter frequency 150.302. The site is situated in the eastern portion of the forest. The mist-net/NLEB capture site was located east of the Pocosin Wilderness and west of Newport, NC along Millis Swamp Road/FS Road 177 at approximately 34.77828°, -76.96162°. The capture site was along the road where it intersects with Juniper Branch, within the Coastal Plain Small Stream Swamp (Blackwater Subtype) natural community. The capture site is surrounded by upland row/managed loblolly pine and longleaf pine. There are several streams that converge in this general area and connect to the Pocosin Wilderness, a large wetland/swamp area. For tree species please refer to the description of mist-net site 2-Carteret in section 4.1.1.

### 4.2.2 – Croatan National Forest Craven County

**Mist-net Site 1-Craven** is the site of a male NLEB captured on 12/18/2017, transmitter frequency 150.340. The site is situated in the northeastern portion of the forest at a NCWRC game land located off of Mill Branch Road/FS Road 170, at approximately 34.027270°, -77.046536°. This site is also the location of the first NLEB captured within the Croatan NF in May 2017 by NCWRC. This site is located approximately 0.5 miles west of Brice Creek and is situated where a forest road intersects with two tributaries to Brice Creek and a wetland/swamp that is surrounded by Mesic Mixed Hardwoods, (*Coastal Plain Subtype*), Coastal Plain Semipermanent

Impoundment, and Coastal Plain Small Stream Swamp, (*Blackwater Subtype*) community types. For tree species please refer to the description of mist-net site 1-Craven in section 4.1.2.

**Mist-net Site 4-Craven** is the site of a male NLEB captured on 12/2/2017, transmitter frequency 150.430. The site is situated in the center of the Croatan NF along FS Road 178 off of Middle Little Road/FS Road 121-2 at approximately 35.00707°, -77.07463°. The capture site borders a large wetland/swamp area north of Catfish Lake, is approximately 0.5 miles west of Brice Creek, and is adjacent to Weyerhaeuser property. The mist-net site was situated within the Coastal Plain Small Stream Swamp (*Blackwater Subtype*) community type. The surrounding area consists of mixed pine and hardwood forested uplands. For tree species please refer to the description of mist-net site 4-Craven in section 4.1.2.

**Mist-net Site 10-Craven** is the site of two male NLEB captures on 2/16/2018 and 2/28/2018, transmitter frequencies 150.100 and 150.180, respectively. This site is situated in the center of the forest along Hunters Creek Road/FS Road 144 at Hunters Creek, approximately 2 miles west of Pond Pine Wilderness and Pocosin Wilderness at approximately 34.80819°, -77.07938°. The county lines for Carteret, Craven, and Jones counties converge in close proximity of this location. The mist-net site was situated within a Coastal Plain Small Stream Swamp (*Blackwater Subtype*) community along Hunters Creek Road where it intersects with Wolf Swamp. The surrounding area consists of upland, mesic, mixed pine and hardwood forests and a managed pine stand. For tree species please refer to the description of mist-net site 10-Craven in section 4.1.2. It should be noted that a discrepancy in the location of the Craven/Carteret county line between the U.S. Forest Service (USFS) map and the NCDOT GIS shapefile exists in this vicinity. For the purposes of this report, we have utilized the USFS line, but show both lines on the attached mapping.

### 4.3 - NLEB Roost Site Habitat Descriptions

Of the five NLEB captured, bat 302 was tracked to roost trees located in Carteret County, bats 430, 340, and 180 were tracked to roost trees located in Craven County, and bat 100 was tracked to roost trees located in both Craven and Jones Counties, which is the first county record for NLEB in Jones County (Figure 10). Community types at NLEB roost sites are described below. Additional roost data are presented in Table 10. Please refer to Figures 8a and 9a-b for the locations of NLEB roosts.

#### 4.3.1 – NLEB 150.430 Roosts A-C, Craven County

This NLEB, captured at mist-net site 4-Craven during session 1, was tracked to three roosts (A, B, and C). Roosts A and C were located within a Bay Forest community type (Schafale, 1990) where the canopy was dominated by the presence of loblolly bay (*Gordonia lasianthus*). NLEB 430 was documented using roost A, a live pond pine, for five days and roost C, a live loblolly bay, for one day. Roost B, a live red maple located within a Coastal Plain Small Stream Swamp (*Blackwater Subtype*) community, was used for six days. Please refer to the description of mist-net site 4-Craven in section 4.2.2 for a description of the habitat for roost C at this locality.

#### 4.3.2 – NLEB 150.340 Roosts A-D, Craven County

NLEB 150.340 was captured at mist-net site 1-Craven during session 1 and was tracked to a total of four roosts (A, B, C, and D). Roost A was a live sourwood located within a Dry-Mesic Oak-Hickory Forest (*Coastal Plain Subtype*) with a canopy dominated by white oak. The understory is

dominated by highbush blueberry, swamp bay, fetterbush, and an assortment of greenbrier species. Roosts B, a live water tupelo, and D, a live bald cypress, were both located within the Coastal Plain Small Stream Swamp (Blackwater Subtype) community. Please refer to the description of mist-net site 1-Craven in section 4.2.2 for a description of the habitat for roosts B and D at this locality. Roost C was a live bald cypress located within a Cypress-Gum Swamp (Blackwater Subtype) with a canopy dominated by large, mature bald cypress and water tupelo, in addition to a few red maples. Standing water between 1 inch and approximately 30 inches deep was present in the majority of this community type. Roosts A and B were used for two days each, roost C was used for six days, and roost D was used for 38 days.

#### **4.3.3 – NLEB 150.100 Roosts A & B, Craven and Jones County**

NLEB 150.100 was captured at mist-net site 10-Craven during session 2 and tracked to a total of 2 roosts (A and B). Roost A is a live sweetgum located within the Coastal Plain Small Stream Swamp (Blackwater Subtype) community. Please refer to the description of mist-net site 10-Craven in section 4.2.2 for a description of the habitat for roost A at this locality. Roost B is a live water tupelo located within the Cypress-Gum Swamp (Blackwater Subtype) community. The canopy is dominated by large, mature bald cypress, with numerous water tupelo and frequent red maple, sweetgum, red bay and swamp bay. The understory is generally sparse, and includes few specimens of fetterbush, Carolina jasmine, large gallberry, dog hobble, and saw greenbrier. Standing water between 1 inch and approximately 30 inches deep is present in the majority of this community type. Both roosts were used for two days each before the transmitter was dropped.

#### **4.3.4 – NLEB 150.302 Roosts A-D, Carteret County**

NLEB 150.302 was captured at mist-net-site 2-Carteret during session 2 and tracked to four roosts (A, B, C, and D). Roost A was in a loblolly pine snag and located within a managed row pine stand (not a natural community) with a canopy dominated by *Pinus* species such as loblolly and longleaf pine and a few scattered sweetgum. Roosts B, C, and D were located within the Coastal Plain Small Stream Swamp (Blackwater Subtype) community along Juniper Branch and Southwest Prong of the Newport River. The canopy is dominated by large, mature water tupelo and black gum, with frequent red maple, sweetgum, red bay, and swamp bay. A few sand live oaks (*Quercus geminata*) were observed at the transition with upland habitats in this vicinity. The understory is generally sparse, and includes few specimens of fetterbush, Carolina jasmine, large gallberry, and saw greenbrier (*Smilax bona-nox*). Standing water between 1 inch and approximately 30 inches deep is present in the majority of this community type. NLEB 302 was initially documented using roost A for three days, and returned to this roost after a period of fifteen days spent in roosts B-D. Roost B was a live red maple used for one day, roost C was a live black tupelo used for two days, and roost D, a live red bay, was used for seven days.

#### **4.3.5 – NLEB 150.180 Roosts A-D, Craven County**

NLEB 150.180 was captured at mist-net-site 10-Craven during session 2 and tracked to four roosts (A, B, C, and D). All four roosts were located along Wolf Creek where standing water between 1 inch and approximately 30 inches deep is present the majority of the time. Roost A, a live bald cypress, and roost D, a live swamp tupelo, were both located within the Cypress-Gum Swamp (Blackwater Subtype) community. The canopy was dominated by bald cypress, water tupelo, and swamp tupelo, with scattered red maple and sweetgum. The understory is generally sparse, and includes few specimens of fetterbush, large gallberry, hemp vine (*Mikania*

*scandens*), doghobble and saw greenbrier. Roost B, a live red maple, and roost C, a live swamp tupelo, were both located within the Coastal Plain Small Stream Swamp (Blackwater Subtype) community. The canopy was dominated by swamp tupelo, water tupelo, black gum, red maple, frequent bald cypress, and a few red bay and swamp bay. NLEB 180 was documented using roost A for one day, roost B was used for 14 days, roost C was used for one day, and roost D was used for five days.

#### 4.4 Summary of Findings – Mist-net Captures

Mist-net sites were chosen by permitted biologists based on optimal habitat and flight corridors. A total of 254 bats were captured, representing ten of the 17 bat species typically found in NC. Five NLEB, the target species, were captured at three locations in Craven County and one location in Carteret County. For Session 1/ fall 2017, four mist-net surveys were conducted in Carteret County, 15 in Craven County, and 23 in Jones County for a total of 42 surveys completed. During Session 2/ winter 2018, six surveys were conducted in Carteret County, 31 in Craven County, and ten in Jones County for a total of 47 surveys completed. Of the 254 bats captured, 75 percent were male and 25 percent were female.

Two NLEB were captured during Session 1/ fall 2017 at two locations: mist-net sites 1 and 4 in Craven County, and three NLEB were captured during Session 2/ winter 2018 at two locations: two NLEB at mist-net site 10 in Craven County and one at mist-net site 2 in Carteret County. Although NLEB were previously documented within the Croatan NF in Craven County by NCWRC in May of 2017, they had not previously been captured within the county or the Croatan NF during the fall or winter, or within Carteret County, NC during any season.

Although no bats showed clinical signs of infection by White Nose Syndrome (WNS), captured species susceptible to WNS were swabbed for the presence of the fungus, *Pseudogymnoascus destructans* (Pd), responsible for the disease. Bat species swabbed included the northern long-eared bat, southeastern bat (*Myotis austroriparius*), big brown bat (*Eptesicus fuscus*), and tri-colored bat (*Perimyotis subflavus*). During Session 1 and 2, 88 bats and one substrate for NLEB 340 roost D cavity were swabbed. The samples have been turned over to Kennesaw State University (KSU) in Georgia for analysis and results will be submitted to NCDOT and USFWS when testing is completed. All captured *Myotis* species were photographed.

Table 10 provides a summary of all bat species captured during mist-netting. Please refer to the figures accompanying this report for the locations of mist-net sites. Please refer to Appendix A for mist-net site photographs, Appendix B and D for photographs of captured bats including NLEB, and Appendix F for mist-net data sheets.

#### 4.5 Summary of Findings - Radio Tracking, Roosts, and Emergence Surveys

As previously mentioned, radio tracking was conducted for all five NLEB captured. All five NLEB were tracked to a total of 17 roost trees located in all three counties (Table 10). Although eleven different tree species were used for roost, the most commonly used were *Nyssa* species, bald cypress and red maple.

Roost trees varied greatly in species, age, condition, DBH, height, and observable crevices available for roosting. With the exception of bat 340, roost D, distance between roosts averaged < 0.50 km. Roosting activities observed were typical of commonly documented NLEB behavior, where roost switching is frequent and trees vary in size and species. Typically, NLEB change roosts every two to five days (USFWS 2014b).

During the course of this study, NLEB 340 exhibited previously undocumented roosting behavior. This bat was captured December 18<sup>th</sup>, 2017 and tracked and documented in four different roosts until February 13<sup>th</sup>, 2018. The bat was verified within roosts on a total of 51 days. On December 31<sup>st</sup>, 2017, NLEB 340 moved > 3 miles (1.069 km) from roost C to roost D in subfreezing temperatures <30° F a few days before a winter snow storm on January 3<sup>rd</sup>, 2018. Although this bat was observed to use four different roost trees, NLEB 340 was documented, via radio telemetry (19 days) and visual observation (16 days), to use roost D for a total of 35 days. During this period, two snow/ice events occurred and temperatures in the swamp where roost D was located remained <30° F the majority of the time. However, temperatures from <30° F up to <70° F were observed on warmer days.

In addition, NLEB 180 moved between four roosts during the 21 days of tracking in Craven County. During this period, NLEB 180 used roost B for a total of 14 days and returned to this roost several times during inclement weather events and when temperatures dropped significantly. In general, NLEB were observed to roost in taller trees with larger diameter at breast height (DBH) during harsh weather events and colder temperatures.

Table 10 provides a summary of radio tracking dates, roosts documented, and emergence surveys performed. Table 11 provides a summary of NLEB roost distances from capture sites for each of the five tracked NLEB. Detailed roost habitat descriptions are provided in Section 4.3. Please refer to Appendices C and E for representative photographs of roost and community habitats, and Appendix G for tracking, roost, and emergence data sheets.

## 5.0 DISCUSSION

During fall 2017 and winter 2018, a total of 89 surveys were conducted within Carteret, Craven, and Jones Counties, North Carolina, within the Croatan National Forest. Surveys were successful in realizing the main objectives of this portion of the research study of the northern long-eared bat in eastern North Carolina. With four captures in Craven County, one capture (new record) in Carteret County, and the documentation of an active roost (new record) in Jones County, two counties were added to the distribution of this bat species in eastern NC (Figure 10). A May 2017 NCWRC NLEB capture record in Craven County was reinforced by this study's four additional Craven County NLEB captures, which confirmed an active NLEB population within this county. All five captured NLEB were tracked to roosts and remained active during warmer periods of both fall 2017 and winter 2018, documenting fall/winter activity. The documentation of NLEB 340 moving >3 miles (4.83 km) in temperatures well below 30° F to a roost tree that was used for at least 35 days during two snow events and several weeks of sub-freezing temperatures provides evidence that NLEB remain active during winter, and may indicate that these bats have behaviorally adapted to select overwintering roosts in large trees. In addition, the observed activity and capture temperatures documented (64.5° F – 51.5° F) during this research project have also provided evidence that NLEB remain in the North Carolina Coastal Plain during the winter and are active during warmer periods throughout the winter. Please refer to Tables 7-10 for more information on capture temperatures.

To note, eight tri-colored bats were captured; three in Craven County and five in Jones County. Both males and females were captured, which suggests the potential of a reproducing population within the Croatan NF. Since the discovery of the fungal disease WNS in 2006, populations of the tricolored bat have plummeted with reported mortality rates of 100 percent in many affected hibernacula (CBD and DOW, 2016). After a 90-day review in response to a petition by the Center for Biological Diversity (CBD) and the Defenders of Wildlife (DOW) to list the tri-colored bat as a Threatened or Endangered species, the USFWS has announced that listing may be warranted and has initiated a twelve month review (Federal Register 2017). Documentation of the tri-colored bat in the Coastal Plain of NC may be important as this may possibly be a refuge for this species to escape the fungus and the associated disease, WNS. Four of the tri-colored bats (males and females) were captured at mist-net site 4-Jones (Crooked Run Road) located on the northwestern section of the forest. In addition, a female tri-colored bat captured during a survey breakdown in Craven County was documented at 38° F (3.33° C).

Also of note, the Croatan NF was conducting a prescribed fire regimen in areas where tracking surveys were being conducted during Session 2 winter 2018. NLEB 302, captured in Carteret County on February 2<sup>nd</sup>, 2018 was being actively tracked in the general area of capture site 2-Carteret and along Millis Swamp Road/FS Road 177 during two separate prescribed fire events. Due to active fires and safety concerns, staff could not enter the area to track this bat to the actual roost tree on February 23<sup>rd</sup> and 25<sup>th</sup>, 2018; however, on these dates, a tracking team was able to follow the transmitter signal of NLEB 302 to observe this bat flying during the day and switching between several trees during both fire events. Although a roost was not documented on February 23<sup>rd</sup>, NLEB 302 was observed moving and switching trees during a prescribed fire along Millis Road. On February 24<sup>th</sup>, NLEB 302 had returned and was documented back in roost 302A. On February 25<sup>th</sup>, 2018 a second fire event was in progress, and NLEB 302 was again observed flying and switching between trees during the fire; therefore, no roost was documented this day. On February 26<sup>th</sup>, NLEB 302 was documented in a new roosting area NE of its capture site in Roost 302B. The roost was located in a riparian area with standing water along Juniper Branch and Southwest Prong of the Newport River. Anecdotal reports were also received from members of the Croatan NF fire crew that bats were observed flying and switching trees during the day during the

February 23<sup>rd</sup>, 2018 fire event. Although bats have often been observed flying out of vegetation during fire events (personal communications with forest staff), it was notable to observe and document NLEB moving and switching to safer areas during such events.

Overall, all captured bat species were observed to be healthy, with no wing damage to indicate WNS. Swabs for analyzing the potential presence of Pd were collected on all NLEB, southeastern bats, big brown bats, and tri-colored bats captured. No little brown bats were captured; therefore, none were swabbed for Pd. A total of 88 bat swabs and one swab of NLEB 340 roost D were submitted to KSU. Results will be sent to NCDOT and USFWS when received.

Although no female NLEB were captured, large sections of the Croatan NF were inaccessible (i.e. remote wilderness areas) and therefore no surveys were conducted in these areas. All NLEB captures and roosting activity were documented on the borders of these large wilderness areas or along riparian corridors (streams and swamps) that connect to these areas that are difficult to access to conduct mist-net surveys. These riparian corridors and inaccessible areas may support a larger population of NLEB in the Croatan NF and provide habitat that is supportive of maternity roosts and the associated females. Additional surveys in this area of the state and during the maternity season are needed in order to fully assess population size and to document a reproductive NLEB population.

Site Description, other than Habitat Info covered on pg 3: mixed/hup/landed / managed / mature / natural medium clutter (3) Sweet gum, loblolly pine, longleaf pine, oak, water oak, community upland pine / managed / mixed flooded / upland mixed pine / hardwood / hardwood											

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Closed early due to temperatures dropping below 45°  
 but was open 3 hours following scope & MEDOT + USFWS  
 guidelines

Project: NCDOT NREB Research County: Carteret Site#: Carteret Nigh# 1 Site Name: Oyster Point FS 183 Date: 12-12-2017

all bat species is not: A...

Mist Net Sites Habitat Info - please circle the option that best fits

Pine / hardwood mixed unforested

Upland bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an average number representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year unmanaged pine stand with a dense gallberry/bayberry understory, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

**bald cypress, turkey oak, red maple**  
**water tupelo, sweet white oak, pine**  
**habitat type: mesic mixed hardwood, coastal plain**  
**subtype, & coastal plain small stream swamp,**  
**backwater subtype**  
**mixed forest/manged/mature forest**  
**Natural/medium clutter 40-75%**  
**upland & bottomland**

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

\* closed early due to temps dropping below 45° but was able to survey 3 hours following scope and NCBOT & USFWS guidelines

Mist Net Sites Habitat Info - please circle the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an average number representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year unmanaged pine stand with a dense gallberry/bayberry understory, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

swamp, blackwater subtype											
Site sketch (label to match Nets/Traps and BD# above)											

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info - please circle the option that best fits

Pine / hardwood (mixed) / unforested

Upland / (bottomland)

Managed (thinned, burned, pine plantation or otherwise disturbed) / (unmanaged)

(Mature forest) / <20 years old forest or cutover

(Natural) (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an average number representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year unmanaged pine stand with a dense gallberry/bayberry understory, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info - please circle the option that best fits

Pine / hardwood (mixed) / unforested

(Upland) (bottomland)

(Managed) (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

(Mature forest) / (<20 years old forest or cutover)

(Natural) (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an average number representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year unmanaged pine stand with a dense gallberry/bayberry understory, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an average number representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year unmanaged pine stand with a dense gallberry/bayberry understory, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Any Other Habitat Notes: mesic mixed hardwoods, coastal plain subtype +  
coastal plain bottomland hardwood, bottomland

So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Site Description, other than Habitat Info covered on pg 3:

sweetgum, loblolly pine, red maple

mixed/upland/managed/mature forest

Natural/medium clutter 40-75%

habitat community type: nonriverine west hardwood forest

Site sketch (label to match Nests/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

MT ES-BIL Data 12-7-2017 MTHSENS V1

Mist Net Sites Habitat Info – please circle the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10-39% cover

(3) medium, 40-75% cover

(4) high, > 75% cover

Any Other Habitat Notes: nonriverine west hardwood forest

 mixed/upland & bottomland/managed  
 mature forest/natural clutter medium  
 loblolly pine, sweet gum, bald cypress, water tupelo, sweet baymagnolia, american holly  
 community habitat type: coastal plain small stream, swamp black water subtype

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year *unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Any Other Habitat Notes: coastal plain small stream swamp, blackwater subtype

\* closed early due to temperatures below 40.

Site Description, other than Habitat info covered on pg 3:						
Mixed/Upland & bottomland / managed						
mature / natural / clutter med(3)						
loblolly pine, sweet gum, bald cypress,						
tupelo, sweet bay magnolia, american holly						
Community type: coastal plain small,						
Stream swamp blackwater subtype						
Site sketch (label to match Nets/Traps and BD# above)						

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).  
ES data KC 3/6/18 bat long 3/8/18 USFWS 3/1/2018

Mist Net Sites Habitat Info - please **circle** the option that best fits

Pine / hardwood / ~~mixed~~ / unforested

~~Upland~~ / Bottomland

~~Managed~~ (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

~~Natural~~ (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10-39% cover

(3) medium, 40-75% cover

(4) high, > 75% cover

Any Other Habitat Notes: coastal plain small stream swamp, blackwater  
subtype

Mist Net Sites Habitat Info - please circle the option that best fits

Pine ~~hardwood~~ mixed ~~unforested~~

Upland ~~bottomland~~

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Mist Net Sites Habitat Info - please circle the option that best fits

Pine / hardwood mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year *unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info -- please circle the option that best fits

Pine / hardwood / (mixed) / unforested

Upland / (bottomland)

(Managed) (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

(Mature forest) (<20 years old forest or cutover

(Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an average number representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year unmanaged pine stand with a dense gallberry/bayberry understory, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info – please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed / (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land) / mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Site Description, other than Habitat Info covered on pg 3: mixed forest / managed / mature forest Natural / medium clutter / upland / bottomland bald cypress, turkey oak, red maple, water sweetgum, white oak, bobolink pine habitat community: mesic mixed hardwood, coastal plain subtype & coastal plain small, stream swamp, black water subtype											
Site sketch (label to match Nets/Traps and BD# above) 											

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info -- please circle the option that best fits

Pine / hardwood / ~~mixed~~ / unforested

Upland / ~~bottomland~~

~~Managed~~ (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

~~Natural~~ (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

 community herbaceous type: coastal plain  
 small stream, swamp blackwater  
 subtype

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

11 - Craven 2/28/2018

Mist Net Sites Habitat Info - please **circle** the option that best fits

Pine / hardwood mixed / unforested

Upland bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10-39% cover

(3) medium, 40-75% cover

(4) high, > 75% cover

Site Description, other than Habitat Info covered on pg 3:

sweetgum, loblolly pine, red maple  
 mixed upland (managed) mature /  
 natural medium clutter  
 habitat community: nonriverine  
 west hardwood forest

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info -- please **circle** the option that best fits

Pine / hardwood / mixed / unforested

Upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest / <20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a *40-50 year unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

(1) sparse/no, < 10% cover

(2) low, 10-39% cover

(3) medium, 40-75% cover

(4) high, > 75% cover

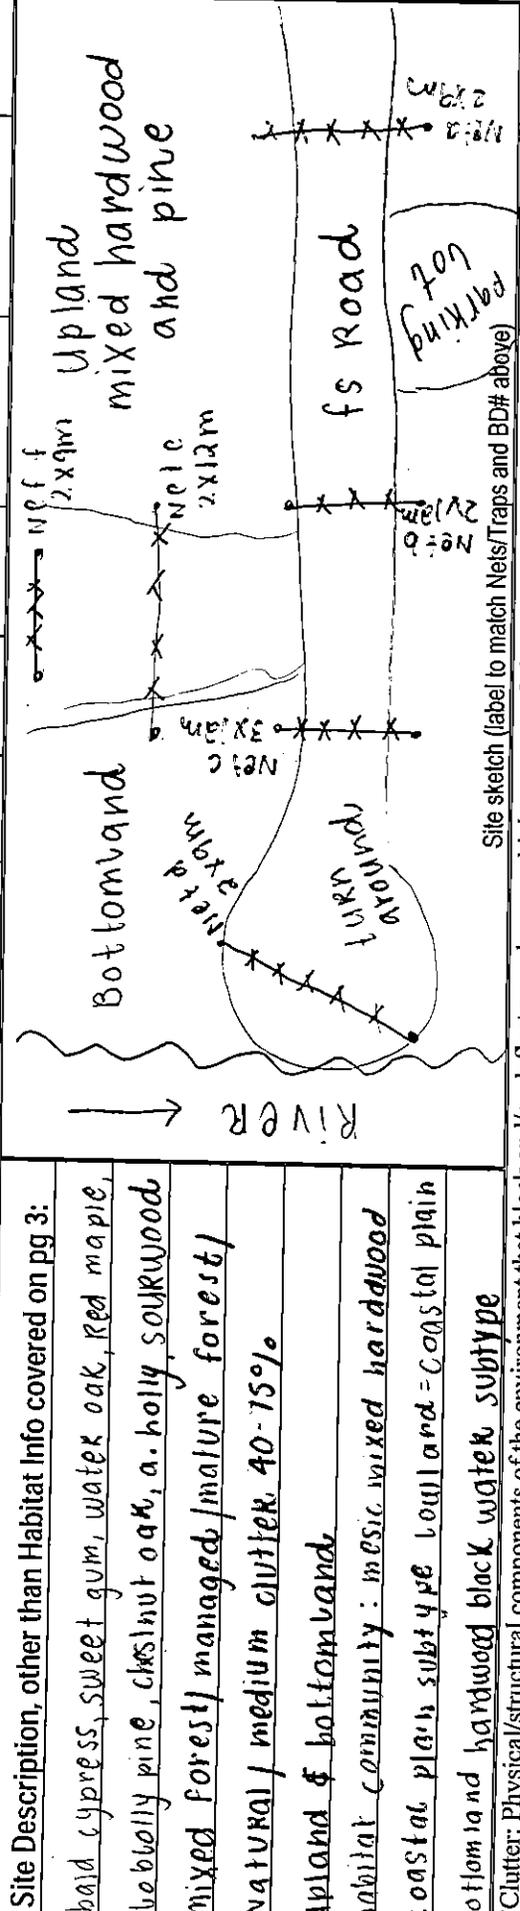

Any Other Habitat Notes: houni verine west hardwood forest

Site Description, other than Habitat Info covered on pg 3:

bald cypress, Sweet gum, water oak,  
 red maple, bobbolly pine, chestnut oak,  
 american holly, sourwood  
 mixed forest/managed/mature/upland  
 Natural/medium clutter 40-75%  
 habitat community: mesic mixed hard wood  
 Coastal plain subtype lowland  
 coastal plain bottomland hardwood subtype

Site sketch (label to match Nets/Traps and BD# above)

\*Clutter: Physical/structural components of the environment that block and/or deflect sound waves; high amounts of clutter can negatively affect ability to detect bat calls. Consider all vegetative strata together when estimating cover (shrub, mid and canopy). For acoustics, record clutter class estimates in a zone of 20 x 50 m in the direction that the microphone is pointed. For mist net sites, record clutter as an average number representing the surrounding forest where all nets were set, not specifically the flyway (see pg3).

Mist Net Sites Habitat Info - please circle the option that best fits

Pine / hardwood / mixed / unforested

upland / bottomland

Managed (thinned, burned, pine plantation or otherwise disturbed) / unmanaged

Mature forest < 20 years old forest or cutover

Natural (>50% wooded), rural (>50% agricultural land)/mixed (primary land use is not wooded or agricultural)

Mist Net Sites Clutter Estimate: record clutter as an **average number** representing the surrounding forest where all nets were set, looking at all strata. So, if you are in a 40-50 year *unmanaged pine stand with a dense gallberry/bayberry understory*, average the strata together and then ask, is it greater than 75% cover or less than? So, let's say the canopy is 65%, mid is 35% and under is 90% (each strata represents its own canopy estimate up to 100%) the average for this scenario would then be 63%, which would put it in the med (3) category. If there is only one strata, a dense monoculture of young pines with 95% cover, then you would only have one estimate and that would fall in the high (4) category. If you are in a fairly mature long leaf pine/wiregrass savanna and the canopy is 55%, mid is 15% and under is 10%, the average would be 27% and you would be in the low (2) category. Think about cover estimates in this context: Physical/structural components of the environment that block and/or deflect sound waves. Don't think about cover in the typical vegetation monitoring sense of how much is shading the ground/veg beneath (vertically). Think of it instead as what would deflect sound waves as the bat moves through it horizontally. If the bat cannot move through it at all then that would be 90-100% like the gallberry understory example.

- (1) sparse/no, < 10% cover
- (2) low, 10-39% cover
- (3) medium, 40-75% cover
- (4) high, > 75% cover

Any Other Habitat Notes: mesic mixed hardwood + coastal plain subtype lowland  
 coastal bottomland hardwood, blackwater subtype

APPENDIX E  
PHASE 4 EMERGENCE SURVEYS

Site Name/#: 4 - Craven      Roost Name/#: 430a

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	1	

\* If any bats return to the roost during the survey, then they should be subtracted from the tally.

**Describe Emergence:** Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

Bat 150.430 emerged at approximately 17:23 and immediately  
flew NE at 31°. The bat did not seem to forage  
near roost.

**USFWS BAT EMERGENCE SURVEY DATASHEET**

Date: 12-21-2017 Surveyor(s) Full Name: Dottie Brown & Drew Powell  
 State: NC County: Craven Project Name: NC DOT NLEB Research Project  
 Site Name/#: Croatan NF <sup>Brice</sup> ~~Forest~~ Roost Name/#: 340 A CROATAN NATIONAL FOREST  
 Lat/Long or UTM of Roost: 35.04175 - 77.06591

Description of Roost/Habitat Feature Surveyed: Sourwood tree w/ small crevice dominated forest & Cypress Swamp

Bat Species Known to be using this Roost/Feature (if not known, leave blank):  
Northern long-eared Bat

Other Suspected Bat Species (explain):

Weather Conditions during Survey (temperature, precipitation, wind speed):

temp / clear with minimal or precipitation

Survey Start Time: 16:30 Time of Sunset: 17:00 Survey End Time: 17:44

NOTE: Emergence surveys should begin ½ hour before sunset and continue for a minimum of 1 hour or until it is otherwise too dark to see emerging bats. The surveyor(s) should position him or herself so that emerging bats will be silhouetted against the sky as they exit the roost. Tallies of emerging bats should be recorded every few minutes or as natural breaks in bat activity allow. Please ensure that surveyor(s) are close enough to the roost to observe all exiting/returning bats, but not close enough to influence emergence (i.e., do not stand directly beneath the roost and do not make unnecessary noise and/or conversation, and minimize use of lights other than a small flashlight to record data, if necessary). Do not shine a light on the roost tree crevice/cave/mine entrance itself as this may prevent or delay bats from emerging. If available, use of an infra-red, night vision, or thermal-imaging video camera or spotting scope and an ultrasonic bat detector are strongly recommended but not required.

Time	Number of Bats Leaving Roost*	Comments / Notes
17:38	unable to see bat leave	bat 340 left roost - noted via telemetry
		did notice two other bats emerging from trees in the immediate area

Site Name/ #: Croatan NF <sup>Briar</sup> ~~Area~~, Roost #: 340A Bat Frequency 150-340

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	None Observed	Emergence noted via telemetry emerged at 44° temp

\* If any bats return to the roost during the survey, then they should be subtracted from the tally.

**Describe Emergence:** Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

was unable to see bat emerging from tree, documented via telemetry, Did observe two other bats emerge from two other trees in the area

Site Name##: Carolina Colours Golf Course Roost #: 340D Bat Frequency 150-340

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	0	

\* If any bats return to the roost during the survey, then they should be subtracted from the tally.

**Describe Emergence:** Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

Used telemetry gear to monitor the bats movement  
during survey. No bats were observed/heard leaving  
the roost.

**USFWS BAT EMERGENCE SURVEY DATASHEET**

Date: 3/16/2018 Surveyor(s) Full Name: Dottie Brown Drew Powell  
 State: NC County: Craven Project Name: NC DOT NLEB research project  
 Site Name/ #: 10-Craven Roost Name/ #: 180D  
 Lat/Long or UTM of Roost: 34.81065, -77.07874

Description of Roost/Habitat Feature Surveyed: Black tupelo / wetland / Black water stream

Bat Species Known to be using this Roost/Feature (if not known, leave blank):  
MYSE

Other Suspected Bat Species (explain): NA

Weather Conditions during Survey (temperature, precipitation, wind speed):

clear, 59°, sunny, calm no wind, no precipitation

Survey Start Time: 18:47 Time of Sunset: 19:17 Survey End Time: 19:50

**NOTE:** Emergence surveys should begin ½ hour before sunset and continue for a minimum of 1 hour or until it is otherwise too dark to see emerging bats. The surveyor(s) should position him or herself so that emerging bats will be silhouetted against the sky as they exit the roost. Tallies of emerging bats should be recorded every few minutes or as natural breaks in bat activity allow. Please ensure that surveyor(s) are close enough to the roost to observe all exiting/returning bats, but not close enough to influence emergence (i.e., do not stand directly beneath the roost and do not make unnecessary noise and/or conversation, and minimize use of lights other than a small flashlight to record data, if necessary). Do not shine a light on the roost tree crevice/cave/mine entrance itself as this may prevent or delay bats from emerging. If available, use of an infra-red, night vision, or thermal-imaging video camera or spotting scope and an ultrasonic bat detector are strongly recommended but not required.

Time	Number of Bats Leaving Roost*	Comments / Notes
19:40	1	roost. ~ Emergence by telemetry. Did not see bat leave

Temp 67°F

Site Name/ #: 10-Crown Roost #: 108-D Bat Frequency 150-180

Time	Number of Bats Leaving Roost*	Comments / Notes
Total Number of Bats Observed Emerging from the Roost/Feature During the Survey:	0	did not see bat emerge

\* If any bats return to the roost during the survey, then they should be subtracted from the tally.

**Describe Emergence:** Did bats emerge simultaneously, fly off in the same direction, loiter, circle, disperse, etc. If a radio-tagged bat was roosting in the tree, at what time did it emerge?

no bat was observed leaving roost, documented by telemetry

FYI

A northern long-eared bat (NLEB) was captured on 12-2-2017 by Dottie Brown USFWS permit # TE94704A-1. An adult male NLEB was captured in the Craven County approximately at 35.00707, -77.07463 within the Croatan National Forest. Surveys are being conducted in coastal NC for the presence of NLEB during the winter months. NLEB will be tracked for approximately 21 days.

**Subject:** Northern Long-eared bat Capture Permit TE48579B-3

Hello everyone,

FYI

A northern long-eared bat (NLEB) was captured on 12-18-2017 by Kristi Confortin USFWS permit # TE48579B-3. An adult male NLEB was captured in the Craven County approximately at 35.027270 -77.046536 within the Croatan National Forest. Surveys are being conducted in coastal NC for the presence of NLEB during the fall and winter months. NLEB will be tracked for approximately 21 days.

Thanks,

Kristi Confortin

Hi all,

It seems this capture is in Craven County and not Carteret County. I documented the county by a map that Forest Service gave me which shows the county line for Craven is north of this site. However this maps county lines are incorrect and Carteret County line is approximately .23 miles to the SE. Gary Jordan pointed it out (thanks Gary) and I pulled it up in Google Earth to confirm. Still the great news is that we captured another NLEB in Craven County.

Let me now if you have any questions.

Thanks

FYI

In accordance with protocols for USFWS permit #TE94704A-1, I am reporting the capture of a northern long-eared bat (NLEB) captured on 2-16-2018 by Dottie Brown. An adult male NLEB was captured in the Carteret County approximately at 34.80819, -77.07938 within the Croatan National Forest. Surveys are being conducted in coastal NC for the presence of NLEB during the fall and winter months. NLEB will be tracked for approximately 21 days.

Let me know if you have any further questions.

Thanks,
